We briefly alluded last week to an inspection of medical equipment that had recently taken place at Lahore, about which we have since been afforded a fuller and more detailed account in the *Civil and Military Gazette* of April 5th last. It appears that Surgeon-Major-General Gore, the Principal Medical Officer of Her Majesty's forces in India, was accompanied by Surgeon-Colonel Thompson in medical charge of the Lahore district, Surgeon-Colonel Calthrop, Medical Store Keeper and lately Principal Medical Officer of the Suakin Field Force, and Surgeon-Major W. A. Morris. The "Tortoise" tent, as adapted to Indian service requirements, was carefully examined. It was found to be much lighter and easier to pack and carry than what is known as the European private's tent. A tonga, with the Tortoise tent applied to it, and fitted to carry one man lying down and two men sitting, is capable of being drawn by one, two, or three ponies. Altogether the tonga is said to form an admirably constructed ambulance conveyance. In addition to the above, the newest pattern jointed stretcher, designed for mule transport, and various other articles were also inspected. The portable field-stove (adopted by the British Government) has been tried and found to give great satisfaction; it is well-contrived, and is carried on a pack animal. A very portable water carrier was also shown, as well as various field rations. We shall be glad to ascertain the result of the inspection of these inventions as regards their practical applicability to Indian field service. It is presumed that a report will soon be published on the subject.

ENTERIC FEVER AT LUCKNOW.

According to intelligence from Bombay enteric fever is prevalent in the Lucknow garrison. The Duke of Cornwall's Light Infantry are the chief sufferers. There are between twenty and thirty men in hospital, and some young officers are reported to have died from the disease. It is, as we remarked some time ago, an interesting fact in the history of enteric fever in India that its periods of seasonal prevalence usually correspond with those preceding and succeeding the rains.

THE OPERATIONS IN SOUTH AFRICA.

The Queen has given orders for the following appointments in recognition of services during the operations in South Africa, 1896:—Surgeon-Captain Charles Henry Hale, A.M.S., to be a Companion of the Distinguished Service Order; and Surgeon-Lieutenant-Colonel Joseph Andrew Gormley, M.D., A.M.S., to be Brigade-Surgeon-Lieutenant-Colonel.

H.R.H. Princess Christian will present certificates of appointment and badges to the members of the Army Nursing Service Reserve at the Royal United Service Institution, Whitehall, on Wednesday, May 19th, at 5 P.M. The Marquis of Lansdowne, Secretary of State for War, will preside.

"Audi alteram partem."

EPSOM COLLEGE.

To the Editors of THE LANCET.

SIRS,—The governing body of Epsom College have lately been confronted by a new difficulty. Boys who from their lack of means have been educated as foundationers, free of all cost, have by ability and industry worked their way to the head of the school, and have won honours at Oxford and Cambridge. In more than one instance the difficulty of the friends finding money to enable the student to take up his exhibition or scholarship has been very great; and quite lately a mathematical exhibition had to be resigned because funds could not be found for the maintenance of the winner to begin his university career. I need not point out what a bitter disappointment it is to a young man of ability, who has proved his mental worth at school and in the keener contest for university distinction, to find himself barred at the outset of his life by poverty. Our experience would lead us to believe that a very moderate amount for the first few terms would clear away all difficulties, for our boys are taught the necessity of self-help as a part of their school training, and we find they practise it. Our struggle is hard to enable us to continue to teach and to support fifty foundation scholars. That these lads are well taught and cared for is proved by their earnest work and their intellectual successes.

May we not ask the aid of those who sympathise with such lads to enable us to raise a small fund to which we might go in case of need, to help on a deserving student and to give him the opportunity of taking up well-won honours, and to enable him to start on his university career with all its untold possibilities in the future. Any money subscribed shall be most carefully expended, and shall be given only to such of our foundation scholars who have proved their worth and really need aid to secure them the advantages of university training. Within the past twelve months our students have just scored their sixth university honour. Gill, who so lately won a mathematical exhibition at Magdalen College, Cambridge, has now gained a mathematical scholarship at Jesus College, Oxford, and Wood has gained a history exhibition of £30 at Saint Catherine's, Cambridge.

We appeal with confidence for aid, and any contributions sent to me for this purpose I shall most gratefully acknowledge. I am, Sirs, your faithful servant,

May 10th, 1897. C. HOLMAN, M.D., Treasurer.

To the Editors of THE LANCET.

SIRS,—With the return of May there comes a distressing catalogue of poverty in the list of candidates for foundation scholars and pensioners in connexion with the above College. For some weeks past cards from individual cases have been arriving, and subscribers cannot be too thankful for the assistance the selection committee gives them in filling in the votes for the most deserving cases. On looking over the lists I find there are forty-two candidates for foundation scholarships (*six* vacancies), twenty-seven for the pensionership (*one* vacancy), and sixteen for the Morgan annuity (*one* vacancy); in all, sixty-five candidates for eight vacancies. On further analysing the list I find but two stated as life governors, one "subscribed a few years," one "many years," one two years, and three who had given donations—nine in all who, during their lifetime, had taken any interest in the institution.

Surely it is time that the claims of this fund should be more generally recognised by the profession, and in the spirit of the old phrase "charity begins at home," I would suggest that an appeal be made for a Jubilee donation of at least 1*s.* from every member of the profession, the sum so collected to be divided between the unsuccessful candidates. The opportunity thus created for making a strong appeal to the profession might be utilised for increasing the number of annual subscribers. It would, I think, be a strong incentive to men to subscribe if the fact of their having done so carried with it a claim to participation in the benefits of the charity proportionate with the amount of money given, the question of eligibility being, of course, gone into equally in all cases. Suppose that, among the candidates for the six vacancies for the foundation, there were two whose fathers had subscribed for ten years or upwards, I would have them elected at once, and let the remainder go to the poll. The widows of the more provident husbands would thus be spared the humiliation and expense of an election. It is no doubt true that those who subscribe are the least likely to require assistance, but the plan suggested, or some modification of it, might attract many who would not otherwise subscribe.

I am, Sirs, your faithfully,

Weymouth-street, W., May 10th, 1897. CHAS. W. CHAPMAN.

P.S.—Should the proposed collection be a success a substantial balance could be given to the College.

PSITTACOSIS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 1st I notice a report from your correspondent in Rome *re* the above, and think you will, perhaps, permit me to make a few observations thereon, as I have exceptional opportunities of observing parrots both dead and alive. Of the former, I have examined some hundreds, of all sorts and sizes, and am unable to confirm your correspondent's assertion as to their peculiar susceptibility to tuberculosis, a complaint of which I have rarely found evidence in the subjects that have been brought under my notice. The principal cause of the enormous mortality that undoubtedly exists among newly imported parrots is due to septic fever more akin to typhus than to typhoid fever; it is communicable by inoculation to pigeons, poultry, and to other domestic birds and animals, but is not by infection only. At the same time the germs of the complaint are most persistent and cling to a cage, or even to a room or part of a room, where a bird has died for months and years, so that the next bird, no matter how healthy when introduced, immediately contracts the disease and succumbs in from three to six weeks, never, as far as my experience goes, surviving the latter period.

Ordinary methods of disinfection are useless, the only reliable plan of purifying a cage being to expose it to the action of concentrated steam in a properly constructed disinfecting apparatus of the Washington Lyon type, after passing through which a previously infected cage is perfectly safe. I have no evidence of this septic fever having been communicated to human beings, or, except by direct inoculation, to any other animals but those of the parrot tribe, and of these only to the species that come from the Gold Coast and adjacent parts of Africa, which alone seem liable to contract it, the principal victims being the ordinary grey parrot, the Pœocephali, and the Agapornes; the Amazons and other American, as well as the Australian, parrots do not appear to be susceptible.

I cannot call to mind, or find any record in my notebook of, a case of tuberculosis occurring in any of the African parrots, and but a very few in parrots coming from America. The last case I met with was one the other day in a large blue-fronted Amazon parrot which had lived for two years in its owner's possession and had been, she asserted, cheerful to the last. It was greatly emaciated, but in very fair plumage, and I found deposits of tubercle, not only in the lungs, but in the liver, and more particularly in the spleen, and the meninges of the brain were also slightly affected. Bronchial trouble, generally terminating in pneumonia, is not at all uncommon among pet parrots and has its origin in the singularly injudicious manner in which the poor creatures are too often treated by their owners, who pamper them with all sorts of unnatural "delicacies" which the birds can scarcely, or not at all, digest, and expose them to draughts and to great and sudden fluctuations of temperature, so that the wonder is, not that some parrots contract pneumonia and bronchitis, but that any escape.

Another practice—very common, too—is to cover the cage of a parrot over very closely at night with a rug, or a blanket, or some thick material or other, that effectually precludes all circulation of air and necessary ventilation, forcing the bird to breathe an atmosphere not only exhausted of its oxygen, but tainted with the exhalations from the bottom of the cage, too often foul, but from the body of the bird itself, so that towards morning the poor creature is in a veritable vapour bath. Then comes the parlour-maid, sweeps, raises dust, throws doors and windows open, whips the cover off the cage, and exposes the bird to a chill. That is the explanation, in ninety-nine

Hosted by Google

cases out of a hundred of the susceptibility of these birds to pulmonary affections, which the strongest of us would contract under similar circumstances. Rationally and naturally treated parrots are very hardy and will live for fifty, seventy, or even a hundred years in confinement. The septic fever that more than decimates newly imported African parrots would not be difficult to stamp out. Originally contracted from insanitary surroundings on board ship, the disease has become endemic in the places where these birds are landed, healthy as a rule at present, but on their introduction to the "emporiums," whence they are promptly retailed to the public, they at once contract the deadly fever, and in six weeks not one of them is alive.

I am glad to be able to report that there are some intelligent and humane dealers whose shops are in a sanitary condition, but others are the reverse of this, and what is wanted in the interest of the birds as well as of the public, who, indeed, are in no danger of contracting the fever from their purchases, is that all shops and emporiums should be periodically inspected, and such as are found to be in an unhealthy condition and a source of infection should be closed, if not permanently, at least until they have been certified to be once more clean and wholesome. With regard to the pulmonary affections of parrots, I greatly doubt their being communicable to human beings under ordinary circumstances, but, of course, if an owner is foolish enough and, I must add, disgusting enough, to kiss the bill of a sick or even of a healthy parrot, to feed it from his or her mouth, and generally coddle it in an imbecile fashion, why, it is possible such a stupid person may contract the disease, but not otherwise, and in such a case I, at least, should feel very much inclined to say "Serve her right."

I think there is not the slightest cause for alarm or that anyone need go into fits about the unhealthiness and risk of harbouring a parrot or parrots. The birds when correctly treated are perfectly hardy, and all but a few of them will live quite well all the year round out of doors in this changeable climate of ours and not be a penny the worse for the exposure, but, on the contrary, remain in robust health and a perfection of condition that is looked for in vain in the poor miserable wretches that are treated like hot-house plants in-doors. I do not mean to say, of course, that it would be possible to turn out a newly imported parrot in mid-winter, for to do so would be tantamount to signing its death warrant; but they can be acclimatised by degrees, and if either allowed their full liberty or turned into an out-door aviary about the end of May or in June there will be no occasion to house them afterwards, as was found by the late Mr. T. Buxton to be the case at Northrepps, where many kinds of parrots—including the grey African with the crimson tail—lived happily and healthily in the woods from one year's end to another, the only drawback to keeping them being that sometimes they took it into their silly heads to break bounds and visit the surrounding country, when they were incontinently shot by cockney sportsmen, who, by the by, do not all reside in the metropolis. If a parrot is rationally treated there is far less risk from its society than there is from that of the average dog or cat, and no one need be under any apprehension of contracting "psittacosis," unless, as I have said, he or she should be stupid enough and disgusting enough to become voluntarily infected by the morbid secretions from an ailing bird, and as many of these are possessed of an immense fund of courage and endurance, and show no symptom of being ill until the last, it is well that all intimate connexion with them should be strictly avoided; and if due care is taken in this respect no one need be under the slightest fear of contracting any complaint, but ordinary rules of cleanliness must not be ignored, and if they are, it is not the parrot, but its negligent owner that should be blamed for any untoward consequences that may follow. Other birds, besides parrots, are liable to epidemic disease that very readily becomes endemic, and is then transmissible by atmospheric infection to other animals, and even to human beings. I refer to the dreaded canary plague, which is a form of splenic fever, near of kin to the gaol fever of former times, that had its origin in crowding and filth, as this terrible disease most undoubtedly has.

Case after case has from time to time been brought under my notice where a canary keeper has lost his entire stock through incautiously buying a new bird at an infected shop, and once an outbreak occurs it can only be stamped out, like the pleuro-pneumonia of cattle, by instantly destroying every bird that shows the least sign of illness and burning the cages and everything connected with them; no form of disinfection is to be relied on in such a case, for even stoving has been found to fail. There is no doubt that this complaint, like the kindred disease known as chicken cholera, is due in the first instance to crowding in wooden cages saturated with the droppings of generations of birds often—too often—dieted on unnaturally stimulating food and kept at tropical heat, or above it, to ensure early broods. The spleen seems to be the principal seat of the disease, it is enormously enlarged, and studded with points of white matter which are not tubercular, but *sui generis*, and the whole system swarms with microbes.

I know of one case of canary plague where some children who lived in the room where the cages were kept contracted a feverish affection, accompanied by a rash that had a superficial resemblance to that of measles, but did not run the course of that disease, though taken for it by the medical attendant (not myself); however, the symptoms, which were not severe, the temperature not rising above 100° F., quickly subsided when the children were moved elsewhere. Every one of the birds, however, about fifty or so in number, died; and after the room had been fumigated and the cages cleansed, thoroughly, as was supposed, and disinfected, a new stock of birds was acquired, but quickly followed their predecessors, and then the fancier gave up in despair. But even the canary plague need be no bugbear for householders if only due attention is paid to ordinary sanitation; but filth always has engendered disease and always will do so, but it sounds to me irrational to condemn the innocent victims when it is really those who by neglect or ignorance of the common laws of health, and especially of the right way of managing birds, who should be blamed. There will be no psittacosis, or canary plague, or chicken cholera either, if the subjects of these diseases are treated properly by the persons who have charge of them, and other pulmonary complaints are also usually due to some breach of a natural law.

I am, Sirs, yours faithfully,

May 8th, 1897. W. T. GREENE, M.A., M.D., F.Z.S., &c.

FASHION IN THE CLIMATIC TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Dr. Wm. Murrell concludes his communication on Phthisis in THE LANCET of April 10th, p. 1018, with these words: "The sleeping cars which convey large numbers of phthisical patients to the Riviera and other popular health resorts at certain periods of the year are not above suspicion, and much greater care should be taken in having them aired and disinfected than is at present the case." Equally consoling was Dr. Heron's speech at the British Balneological and Climatological Society on "The Climatic Treatment of Phthisis." THE LANCET of Feb. 27th reported from it as follows: "Patients, he thought, went to the Riviera with its delightful climate, to slide down to the grave as quietly and comfortably as they could; he did not think that life there was calculated to cure tuberculosis." After practising a whole season in Mentone, and treating many and various maladies, I find I have not had a case of phthisis. A leading medical man who has practised here for many years says the proportion of cases of phthisis he sees is not greater than in an ordinary practice in England. Where are these large numbers of phthisical patients who, Dr. Murrell considers, are rendering sleeping cars suspicious? Where are those whom Dr. Heron pictures tobogganing quietly and comfortably to the grave? In spite of receiving these imaginary crowds of invalids to put up our mortality, there have been, since the season commenced in October, but four deaths among the English and Americans from all causes, one English and one American only having died from phthisis, and Mentone has been exceptionally full of people.

Visitors are commonly warned by ignorant people, including their medical advisers, that Mentone is crowded with invalids and that it is well to at least sleep out of it. They have often told me when here, however, that there are far more invalids to be seen at Hastings, Bournemouth, and other English health resorts. At the commencement of the year four members of Guy's Hospital staff were here with their wives, and made an average stay of three weeks. Must it be presumed that this was for the purpose of

Hosted by Google

contracting phthisis themselves or giving their wives a chance of taking it? On the contrary, Mentone is now probably safer in this respect than England, for in the event of any patient dying here from phthisis or other infectious disease his room is rigorously disinfected and left perfectly safe for any subsequent occupant. Shortly we hope to similarly have all rooms disinfected which have been occupied for any period by phthisical patients. As regards the streets, Cornet of Berlin[1] has shown that "the dust in streets obtained from places where consumptives were wont to spit might be neglected so far as any risk of tuberculous infection is concerned." The majority of phthisical patients one meets here are French, and they generally avoid the hotels frequented by the English or take private lodgings. One laments, as one sees the great improvement many of them make, that the fashion for Switzerland, now almost a mania, deprives many English patients for whom the Riviera may be specially suited of their best chance of recovery. When the fashion again sets this way it is to be hoped for the patients' sake it will not take the indiscriminate form for Mentone which it now does for Switzerland, or that the fear of contracting phthisis in Switzerland may not commence there when all the patients again come here.

I am, Sirs, yours truly,

Mentone, France, April 24th, 1897. D. W. SAMWAYS.

"SENILE DECAY: ITS CAUSES AND TREATMENT."

To the Editors of THE LANCET.

SIRS,—Professor Allbutt, in his letter on the above subject,[1] touches upon one of the most fascinating problems in biology—Why do organisms become senile? Every organism tends at a certain period of its existence to pass into a phase of decay whose natural termination is death. We are too much in the habit of thinking we have explained this fact by referring it to "wear and tear," by assuming that the body wears out much as a locomotive does. Such an analogy is fallacious. Wear and tear operate as much during the years of growth and development as afterwards—during those years, in fact, when the organism, far from wearing out, is actually perfecting itself. Again, if the limit of life were essentially determined by wear and tear we should expect to find the various species of a class becoming senile at much the same age; but such is not the case. A man is no older physiologically at fifty than is a dog at ten, and this would surely not be the case if the length of the vital span were fundamentally determined by wear and tear. It is possible that an immortal organism might under certain conditions evolve—one, namely, which should never pass into the phase of senile decay. Inasmuch, however, as physical immortality would not be beneficial to species, a limit has been put upon the life of every organism, this limit differing with various species, and being determined by the exigencies of each species as a whole. Thus we may assume that it is of advantage to the human species for its members to live for a comparatively long period, and to the canine species for its members to live a comparatively short time. These considerations suggest that every organism is endowed with specially acquired mechanisms for ensuring the occurrence of senility, and that if such mechanisms had not evolved, there would be a tendency for every organism to be immortal.

Assuming the correctness of this view, we have to inquire into the nature of these mechanisms. I fancy I see manifold processes at work tending to induce senility. It does not seem improbable that modifications in "internal secretions," whose influence on nutrition we now know to be considerable, may help to initiate senile decay. Another causative factor is probably furnished by the vascular system. It has been well said that a man is as old as his arteries. May we not modify this statement and say that the physiological age of an individual is largely determined by the condition of his arteries—that the arterial system takes a large part in initiating and sustaining the process of senile decay? Thus an extremely high peripheral resistance in the shape of narrowed arteries causes the heart to give way and the arteries to degenerate, and with narrow arteries and a weak heart the tissues are imperfectly supplied with blood; whereupon there ensues a struggle for existence among the tissue elements, the hardy and lowly organised connective elements surviving at the expense of the delicate and more highly organised parenchyma: senile fibrosis occurs. We thus see how the vascular system may help to initiate and set the pace of senile decay, and in this connexion the observations of Professor Allbutt and Dr. Savill are of great interest. Trusting you will excuse the incompleteness of these remarks, which I cannot in the limits of a letter hope to make more than suggestive,

I am, Sirs, yours faithfully,

Wimpole-street, May 9th, 1897. HARRY CAMPBELL.

[1] THE LANCET, May 1st, 1897.

"NOTES ON ONE YEAR'S SURGICAL WORK."

To the Editors of THE LANCET.

SIRS,—Mr. Symonds will agree that the "practical result" at which the surgeon should aim is a cure. John Hunter wrote: "For what I call a cure is an alteration of the disposition and of the effect of that disposition, and not the destruction of the cancerous parts."[1] For "cancerous" let us read "painful" and apply this to the cases of flat-foot with hallux flexus reported by Mr. Symonds. He resects the first metatarso-phalangeal joint, the wound heals, and the pain ceases. He has altered an effect, but this has involved destruction of an important joint. What has he done to alter the disposition which caused the trouble with which he was called upon to deal?

Permit me now to offer some "theoretical considerations." The plantar arch, like other parts of the body, is maintained in position by the muscles acting upon it; the agency which moves, in moving sustains. Here an important agent is the long flexor, acting on the great toe and serving as a bow-string or tie-rod to the arch. This toe has its plane of movement obliquely upwards and outwards, downwards and inwards, its position of rest tending in the former direction. If in the median-pointed boot it be unfortunately packed beneath the second toe and it becomes so fixed, it is never in a position of rest, and, so far as it can move at all, movement must be in a plane for which the joint at its base is not adapted. A condition known either as hallux flexus, hallux rigidus, or hallux dolorosus results, the several features giving these alternative names being easily explained. Action of the long flexor giving pain it is suspended, and the plantar arch sinks for want of the bow-string or tie-rod influence which action of this muscle affords. Thus we get flat-foot "complicated," as Mr. Symonds would say, with hallux flexus. I prefer to say associated, for both are the effects of a common cause, defect of function. The indication, as I see it, is to restore functional activity as soon as conditions permit, and this under the best physiological conditions. I see such cases recover so as very soon to permit of active life, the feet ultimately attaining a functional excellence hopelessly impossible after resection of the metatarso-phalangeal joint.

This operation, even in cases of flat-foot with hallux flexus, is, as I find, unnecessary, and therefore, in my view, unwarrantable; that it should be chosen in "uncomplicated" cases is to me distressing. Mr. Symonds does not explain how his operation restores the flattened arch, or whether he bases his prediction of permanence on results of operations in former years. For myself, I am not afraid of being called theoretical, but in this matter I can appeal to "practical results." It is more than thirteen years since I published[2] cases of flat-foot treated by renewal of function which even then had stood the test of ten years of active life. I am ready to show others where the patients and their friends can be interrogated as to whether published descriptions are in accord with facts. I never in these cases fear a relapse, being assured of an "alteration of the disposition" and that the Hunterian definition of a cure has been completely fulfilled. I am, Sirs, yours faithfully,

Gloucester, May 8th, 1897. T. S. ELLIS.

[1] Quoted from Sir Spencer Wells. The passage occurs in Hunter's Lectures on the Principles of Surgery, vol. i., p. 625, Palmer's edition, 1835. For the reference I am indebted to Mr. Stephen Paget.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—Dr. H. Charlton Bastian quotes the following from me:—"Every man individually *acquires* the faculty of

Hosted by Google

language and of bi-pedal progression in an erect posture: neither of these is instructive or inborn and therefore transmissible, and both result from the fact that the one generation acquires them by imitation from the preceding generation." He adds: "This is a very dogmatic statement against which much may be said." Put simply the statement to which Dr. Bastian takes exception amounts to this: that every child *learns* to speak and walk, and it carries the implication that except men did so learn no man could speak or walk. Such is the statement which in the light of every-day experience Dr. Bastian thinks "very dogmatic." He himself is apparently of opinion that men do not *learn* to speak and walk—i.e., that they do not *acquire* the faculties of language and of bi-pedal progression, but that these arise, or would arise, in the individual in the absence of all experience. He declares that he is in agreement with Mr. Herbert Spencer in so far as a belief in the transmissibility of acquired traits goes, and quotes his own Lumleian Lectures and his well-known and most admirable book, "The Brain as an Organ of Mind," in which, after referring to certain instances of what he calls "deferred and untaught" speech and of "untaught" walking, he says: "No explanation of such a fact seems possible except on the supposition that speech has now become a truly automatic act for human beings, and that if children do not speak at birth this is in the main due to the circumstance that their nervous systems are still too immature."[1] I cannot do better than preface my reply to Dr. Bastian by again quoting some wise advice which Mr. Spencer has given, but not always followed. "Clearer conceptions of these matters would be reached if, instead of thinking in abstract terms, the physiological processes concerned were brought into the foreground."

A language consists of words—nouns, verbs, conjunctions, &c.—all of which are different in different languages. To possess the power of articulate speech it is essential to have a knowledge of a set of these words, of their inflections, of their meanings, and of their proper arrangement in sentences. Now let me appeal to your readers—nay, to Dr. Bastian himself—and ask, How did this knowledge of words, &c., arise in his mind? Did he learn it? Did it arise in him as a result of experience? In other words, was it acquired? Or was it congenital? In other words, did it arise in his mind spontaneously and apart from all experience? For instance, did he, in his childhood, learn that the arbitrary sound "brick" designated a certain object, and the arbitrary sound "elephant" another object, or did the knowledge arise spontaneously in his mind? I think the great majority of your readers would reply that in their own cases they learned (i e, acquired) all these things; but Dr. Bastian, to judge by his writings, would say, "No. My knowledge of these things is congenital, not acquired. If I had never heard of bricks and elephants I would yet have applied those particular sounds to those particular objects. If I had never heard a spoken word yet would I have discoursed in good set terms of the objects around me. In the absence of all experience I would have had a knowledge of words, of their inflections, of their meanings, of their arrangements in sentences." Presumably Dr. Bastian would also have had a congenital knowledge of the objects to which words are applied, since to know the names of things implies some knowledge of the things themselves; presumably, also, he would have used spontaneously that set of arbitrary sounds which in the aggregate constitute the English language, for he speaks of an "untaught" English child who said, "What a pity,"[2] and of a Greek boy, likewise "untaught," who said "Αηθρωπε μὴ κτεινε Κροισον."[3]

Dr. Bastian forgets that infants of one race—e.g., negro—reared by individuals of another race—e g., British—speak solely the language of their educators, not their progenitors, whereby is supplied convincing proof that language is acquired, not inborn; for, of course, the negro's ancestors did not apply the sounds "brick," "elephant," &c., to the objects to which the English apply them, and to which the negro child taught by the English applies them. But even more convincing proof is supplied by Dr. Bastian's own writings. He says: "The most important of these congenital defects is deafness, which of itself entails mutism, the individuals thus afflicted being known as 'deaf-mutes.' It must be borne in mind, however, that this mutism or dumbness may also be brought about by absolute deafness occurring from any cause after birth, but before the child has begun to talk, or even after it has learned to talk, up to the fifth or the seventh year."[4] Thus, when the channel (hearing) through which the child acquires a knowledge of speech is closed, the child remains for ever mute, even though the organs of speech, including the nervous mechanism, be perfect; whereas were Dr. Bastian's hypothesis correct congenital deafness ought not to entail mutism. He himself actually uses the word "learned" which, of course, implies acquirement. We must conclude, therefore, that though the *power of acquiring* language, like the power of acquiring a knowledge of letters or of mathematics, or of architecture, or of geology, &c., is inborn, yet language itself, like a knowledge of letters, &c., is never inborn, but always acquired. Indeed, I think that if Dr. Bastian will consider the matter a little he will find reason to conclude that this power of acquiring mental traits, this mental receptivity, is that which constitutes man's special pre-eminence over lower animals, from which, on the other hand, he is also distinguished by the meagreness of that which is mentally inborn or instinctive in him. I think he will further conclude that thus, also, is every higher animal distinguished, to a greater or lesser extent, from a lower animal. Just as regards language, so it is as regards bi-pedal progression. The child is born with little or no power of coördinating its muscles, but gradually *through use and after long practice it acquires* such perfect powers of coördination that it is able to stand and walk. Without use (i.e., exercise) the very limbs of the child do not develop, as is the case in infantile paralysis. I think Dr. Bastian will agree with me that all that arises as a result of use is to be regarded as acquired. Therefore that very degree of muscular development which enables the child to walk is acquired. I have not space to go into this and other kindred matters here; but if Dr. Bastian will so far honour me he will find them discussed at length in my work, "The Present Evolution of Man" (pp 88–93, 108–121).

As regards the instances which Dr. Bastian gives of "deferred and untaught" speech and bi-pedal locomotion, I confess I am puzzled, for I do not follow his line of argument. He says that certain children within his knowledge did not speak or walk till a later period than the common, and then manifested their powers somewhat suddenly. But had not these children the same opportunities of learning as other children? It seems they had more It appears to me merely that they were somewhat slower than other children. I can cap his anecdote of the English boy who said "What a pity," when his toy was broken. A child of English parentage that I knew in New Zealand crawled to the top of a little heap of firewood and then suddenly said as his first words, "Capitenni now," which, as I understand, is an expression of triumph in the Maori language[5] and which, though frequently used by his brothers and sisters was, of course, never used by his ancestors, and therefore could not have been inborn in him.

I am, Sirs, yours faithfully,

Southsea, May 3rd, 1897. G. ARCHIDALL REID.

A CASE OF ABDOMINAL OBSTRUCTION.

To the Editors of THE LANCET.

SIRS,—The following case seems to me of interest in connexion with the case of intestinal obstruction under my care, an account of which was published in THE LANCET of May 1st, 1897:—

A small, undersized boy of sixteen, was admitted to the Stratford-on-Avon Hospital on Feb. 21st, 1897, having suffered from symptoms of obstruction for seven days previously. No hernia could be detected at either ring. The left testicle was in the inguinal canal; the right was undescended. There was considerable distension of the abdomen. As the boy's state was critical laparotomy was performed shortly after his admission, and immediately after consultation with other members of the staff. The usual median incision gave vent to a considerable quantity of blood-stained serum. No hernia was found in the pelvis. The incision was then extended up to the umbilicus, when a coil of distended and injected intestine was found passing through a hole in the mesentery in the neighbourhood of the

[5] I cannot pledge myself to this. The expression was used by the child's companions, and I was told it was from the Maori.

Hosted by Google

cæcum. The constricted intestine was reduced with very little difficulty; and the case admits of very little further description, as its progress to recovery was uninterrupted. A glass drainage-tube was inserted for the first twenty-four hours, and then removed. He left the hospital, with the wound soundly healed and wearing a belt, on March 22nd. This case is of interest in connexion with the one previously published. Again I found an obvious constriction of the bowel, released it, and had the patient removed to a warm bed as rapidly as possible. Writing this some months after the occurrence of the case above referred to, I am still of opinion that I should not have been justified, in either case, in turning out the whole of the intestines to search for further possible obstructions.

I am, Sirs, yours faithfully,

HARRY LUPTON, L.R.C.P. LOND., M.R.C.S. ENG.

Stratford-on-Avon, May 10th, 1897.

"THE HOSPITAL REFORM ASSOCIATION: REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON."

To the Editors of THE LANCET.

SIRS,—Your sense of justice will, I am sure, permit me to reply to the letter signed by Dr. Sibley and Dr. Snape. It is no fault of mine that they called at the hospital three times without finding me at home, but rather theirs for not making an appointment by which their fruitless journeys might have been obviated. But, perhaps they had an object in making surprise visits. However, this point is irrelevant and it offers no excuse for the shortness of their visit to this or any other hospital, while the hasty character of the inquiry affords the reason for the report being no more thorough, and of no greater value, than that of any that have gone before. Dr. Sibley and Dr. Snape imply that I volunteered additional information. On the contrary, I received a letter from one of them, enclosing me the notes they had made on this hospital, with a request that I would correct any mistakes and make any additions necessary. Thereupon I made one or two corrections in their figures and to their "Remarks" I added the following words:—"That the majority of these patients sent by doctors are in a much better position of life than the patients not so recommended. The patients are not merely sent for a diagnosis but for treatment." These words were omitted from their published "Remarks." It was this omission that I complained of, and your leading article of April 24th justifies me in the belief that the omission was an important one.

Indeed, I feel so strongly on this point that I am making inquiry as to the number of patients sent by medical men to those hospitals upon which Dr. Sibley and Dr. Snape have reported. Already I find that at nine alone no less than 17,000 patients, out of a total of 54,000 treated in a year, were recommended by medical practitioners. At seven of the institutions the evidence is very clear that the majority of the patients sent by medical men were in a better position of life than those not hailing from such a source. Therefore the assertion so often made and repeated that special hospitals injure the general practitioner must be admitted to lose much of its supposed force, whilst the source of hospital abuse is proportionately diverted.

I am, Sirs, your obedient servant,

RICHARD KERSHAW, Secretary.

Central London Throat and Ear Hospital,
Gray's-inn-road, May 10th, 1897.

THE SKIAGRAPHY OF THORACIC ANEURYSMS.

To the Editors of THE LANCET.

SIRS,—Dr. Dalgarno and Dr. Galloway are to be congratulated on the successful skiagraph of a thoracic aneurysm which was printed in THE LANCET of May 8th. It is especially interesting and valuable inasmuch as it verifies the fluorescent screen work, which will naturally be the method most usually employed on account of its simplicity and rapidity and also, in most cases, its greater certainty; for a photograph of an aneurysm which requires a long exposure may very easily be spoilt by a slight movement. Since I first showed that thoracic aneurysms could be diagnosed by means of the fluorescent screen,[1] I have examined a great many more cases, and have always been able to see the outline of the tumour quite plainly, and am now quite convinced that in these cases an examination by the Roentgen rays will often prove a valuable addition to the other methods of examination usually employed. In some cases a doubtful condition may be made clear, and in others the diagnosis is still further confirmed.

I am, Sirs, yours faithfully,

H. CAMPBELL THOMSON.

Queen Anne-street, W., May 10th, 1897.

URIC ACID IN THE BLOOD.

To the Editors of THE LANCET.

SIRS,—Dr. Luff's statement that blood contains no uric acid does not appear to be justified by his experiments. One would imagine that blood contained just enough uric acid to supply the necessary eight to ten grains daily. An average proportion of 1 in 1,000,000 would more than suffice for this; hence in 500 c.c. of blood it is necessary to show that not even half a milligramme of uric acid is present. I fail to see how this can be proved by a process in which the error of estimation is from one to two milligrammes, apart from the difficulty in extraction.

I am, Sirs, yours faithfully,

Norwood, May 8th, 1897. DONALD F. SHEARER.

THE GENERAL MEDICAL COUNCIL AND THE MIDWIVES QUESTION.

To the Editors of THE LANCET.

SIRS,—As I owe it to my constituents to let them know why there is no practical use in my attending the May Session of the General Medical Council with the view of trying to settle the above vexed question, will you kindly insert the enclosed copy of correspondence which has passed between myself and Sir R. Quain.

I am, Sirs, yours truly,

Liverpool, May 11th, 1897. ROBERT R. RENTOUL.

78, Hartington-road, Liverpool, S.,
May 8th, '97.

Sir R. Quain, Bart.,
Pres. G. M. Council.

DEAR SIR,—On April 26th, '97, I sent to you a Notice of Motion requesting that such be placed upon the agenda paper for the May Session of the G. M. Council. The following is a copy of that motion: "Draft Bill to Provide for the Compulsory Registration of Midwifery Nurses and existing Midwives as Midwifery Nurses, and for the recognition of existing midwives as such. It will be moved by R. R. Rentoul and seconded by W. Thomson. That the following Midwifery Nurses Training and Supervision Draft Bill be now adopted by the General Medical Council. That a copy of such Draft Bill be now forwarded by the Registrar to the Privy Council, the Local Government Board, and to the medical journals." I also sent you a copy of my Draft Bill.

On April 29th you acknowledged the receipt of the above Motion and Draft Bill, and you refer me to the resolution of the G. M. Council of Nov. 29th, '89, which states that the Council "would not be able to discharge, and would therefore not be prepared to undertake, any duties of detail as to the registration of midwives or as to the local arrangements for licensing and controlling them," but that the Medical Council "would, if the Government so wished, be willing to advise as to the general rules of education, examination, and discipline which ought to be established." You also wrote that as "this resolution was re-affirmed by the Executive Committee and transmitted to the Privy Council on Feb. 22nd, 1897, in answer to a communication seeking the opinion of the General Medical Council on the Midwives Registration Bill introduced into the House of Commons on Feb. 9th, it would not be competent for any member to enter upon a discussion of this question until the decision arrived at on that date and transmitted to the Privy Council has been rescinded."

On April 30th I replied to yours and stated that my Draft Bill is drawn up and based upon the Resolution of Nov. 29th, '89; that it proposes to place no work whatsoever upon the G. M. Council except to approve or otherwise of the Regulations to be drawn up as provided by the Bill. On May 3rd you replied "that all the Resolutions passed by the General Council on Nov. 29th, '89, on the subject of the registration of midwives had reference to the relation of the Council to the Government, so that while in the Resolution to which you have been already referred the Council speaks of being willing to advise any department of Her Majesty's Government on the subject, so in the Resolution to which you probably refer as the basis of your notice of motion it is the Government upon whom the Council urges the importance of passing into law some measure for the education and registration of midwives." On May 4th I replied to yours and pointed out that as the G. M. Council is "willing to advise" I contend that "no practical person can expect a Government to draft a sensible Bill upon a question *re* midwifery nurses registration." I also stated to you that my object was "to *show* the Government that the G. M. Council is not content merely

[1] THE LANCET, Dec. 12th, 1896.

Hosted by Google

with passing resolutions." At the same time I returned my Draft Bill to you, and again asked you to agree to my above notice being placed upon the agenda paper. On May 5th you replied "that the notice of motion you have forwarded is *so entirely opposed* to the views entertained by the G. M. Council and its Resolutions expressing its opinions, it cannot be placed on the agenda paper, and that the only notice of motion that could be entered on it, if you so wished, on the subject would be one to rescind the Resolutions previously adopted."

I cannot adopt your suggestion, coming as it does from one who has publicly offered the greatest opposition to my efforts when opposing midwives registration, to the proposed increase in the number of Direct Representatives upon the G. M. Council, and from one who is opposed to the very principle of such representation. To your assertion that my notice of motion is "so entirely opposed" to the views of the G. M. Council I take direct objection. The above Resolution of 1889 is one which I accept as having been passed with the view of registering midwives with the duties of midwifery nurse, or nurse tender, and not of an inferior order of midwifery practitioners. It has been said that the Midwives Bill of Feb., 1890, was passed upon this Resolution. Clause 5 of that Bill proposed that a midwife should be empowered to recover any fee or charge in court "for the performance of *any* midwifery operation." I feel certain no Member of the G. M. Council could affirm that the Resolution of '89 encourages any such proposed ghastly legislation. Again, when in 1895 the Midwives Bill of that year was before the G. M. Council, it was moved by Sir W. Turner, and seconded by Sir W. Foster—"That the word 'midwife' should be struck out of the title of the Bill and out of the several clauses, and that the term 'midwifery nurse' be substituted for it." This amendment was defeated only by two votes—14 voting against it, 12 for it, 2 not voting, and 2 being absent. This fact shows that the G. M. Council would not be opposed to discussing, and perhaps adopting, my notice of motion and draft Bill, and also that you are in error in stating that my notice is "so entirely opposed" to the views of the Council.

Again, I need not refer you to the result of the 1896 election of Direct Representatives to the G. M. Council, when the Direct Representatives of Scotland and Ireland stated they would oppose the so-called registration of midwives; and also when the Practitioners of England and Wales elected two Representatives because they opposed the so-called registration of midwives, and when the Representative who had been elected in 1891 at the head of the poll was placed at the foot in 1896. All these facts compel me to enter the gravest objection to your suppressing my notice of motion, and to your studied insult to my constituents—actions which I contend are absolutely unjustifiable, and which will reflect the greatest discredit upon a Public Medical Authority established by Act of Parliament. This I shall leave each Practitioner to judge for himself. Personally I feel your action will give a greater vitality to the opposition to midwives' registration. Had you placed my notice of motion upon the agenda paper I would have asked that a day be named to discuss it, as I could not well attend the May Session of the Council for more than one day.

I am, Sir, yours truly,

ROBERT R. RENTOUL,
Senior Direct Representative, G. M. Council.

THE LAW OF, AND PRACTICE IN, LUNACY.

To the Editors of THE LANCET.

SIRS,—While I have certainly no reason to complain of the courteous and favourable, if discriminating, review of the above work in your issue of the 1st inst., I shall be glad if you will kindly allow me to point out that all the reported cases of actions or proceedings against medical men in connexion with the detention of lunatics are dealt with under Sections 315 and 330 of the Acts of 1890 and 1891—the only place in which, according to the scheme of the book, they could be introduced.

I am, Sirs, yours truly,

Garden-court, Temple, May 10th, 1897. A. WOOD RENTON.

HOSPITAL PROVISION FOR MEDICAL CASES IN CHESTERFIELD.

To the Editors of THE LANCET.

SIRS,—We have a population of about 120,000, and yearly increasing, without any provision for medical cases nearer than Sheffield or Derby except the union hospital. For the last quarter of a century I have been advocating the necessity for a medical infirmary, but hitherto without success. We have an excellent surgical hospital for sixty patients, admirable in all its arrangements, quite up to date, and second to none in the provinces. By the rules and original constitution of the hospital medical cases are excluded, and a majority of the governors are against taking any steps to alter this rule although efforts have from time to time been made in this direction. We had a town's meeting this week, convened by the Mayor, and I said that this Diamond Jubilee year was a fit and proper time for endeavouring to supply this great and urgent want. A Volunteer drill-hall was almost unanimously selected to commemorate the Diamond Jubilee, and it was agreed that any sum remaining after entertaining the aged poor and children should form the nucleus of a fund for the medical infirmary. I am of opinion that the infirmary should have taken the first place on the ground of humanity in accordance with the known wish of Her Most Gracious Majesty the Queen and His Royal Highness the Prince of Wales. I have often said that a poor man suffering, say, from pneumonia or acute rheumatism, is in more need of hospital treatment than his fellow workman who is admitted for a simple fracture. I think you will agree with me that it is a scandal and a disgrace that such an institution has not long ago been provided for this town. I think I am correct in stating that it is the only place in England with such a large population where such a state of things exists.

I am, Sirs, yours faithfully,

JOHN ROSE, M.D.,
Honorary Consulting Surgeon, Chesterfield and North Derbyshire Hospital; Staff Surgeon, Royal Navy (Retired List).

Chesterfield, April 24th, 1897.

MERCER'S HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I write for your advice under the following circumstances. The governors of Mercer's Hospital of this city (Dublin) dismissed the whole medical and surgical staff of the institution without assigning any cause; they then notify to these dismissed honorary officials that they are eligible for re-election and request them to continue to discharge their duties until the fresh appointments are made. The power of the governors to dismiss their honorary medical staff will be the subject of a lawsuit ere long I may further add that the governors are co-opted, and it may fairly be said that their conduct towards the medical staff has not the approval of the subscribers to the funds of the hospital. Now I wish to know, Is it in accordance with the traditions of the medical profession that gentlemen should apply for the vacancies, if any, thus created? Am I justified in the sight of my professional brethren in assisting the governors to insult our profession by treating its members as messenger boys by dismissing them without showing cause and thus degrading them, as far as in their power lies, in public opinion? That these gentlemen who have been thus summarily dismissed are fully capable of discharging the duties of the position they occupied is shown by the governors notifying to them that they are eligible for re-election. To me the duty of supporting my professional brethren appears plain; but when I learn that already candidates are in the field—men holding good positions professionally and socially—I begin to question my judgment in the matter and I naturally appeal to THE LANCET for guidance. Of course, it is just possible that the governors are acting *ultra vires;* but even if they are, and the present staff of Mercer's is honourably re-instated (?), what are we to think of those who assist to discredit the medical profession in the eyes of the public?

I am, Sirs, yours truly,

May 11th, 1897. F.R.C.S.I.

*** These vacancies should not be applied for save by the late staff, who are thoroughly conversant with the details of an extraordinary situation.—ED. L.

"ON CERTAIN SYMPTOMS OF SPINAL CORD AFFECTION IN BICYCLE RIDERS."

To the Editors of THE LANCET.

SIRS,—The article on the above subject in THE LANCET of April 17th has called forcibly to my mind several cases of retention of urine and numbness in the penis and perineum brought to my notice during the cycling season, and in every instance I traced the cause, not to cycling *per se*, but to the dangerous wedge-shaped article usually supplied with the machine and called a saddle.

In each case I, instead of ordering a discontinuance of cycling, suggested a trial first of the Henson anatomical or peakless pneumatic saddle, the invention of a medical man, who is also an experienced cyclist. In every instance the result has proved most satisfactory. I feel that this subject deserves far more attention from the profession than it has hitherto received, and I should like to learn the experience of others in this direction.

I am, Sirs, yours faithfully,

May 11th, 1897. CYCLING SURGEON.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

X.—LEICESTER.[1]

Recent but Ineffectual Attempts to deal with Abuse.—Some Flagrant Cases.—Preponderating Influence of the Working-class Subscribers.

AT Leicester the question of hospital abuse holds only a secondary place in the list of grievances affecting the medical profession; the clubs, and more especially the Provident Dispensary, have a far greater effect in reducing the number of patients who should consult the general practitioner. Nevertheless, it is freely acknowledged that there is some hospital abuse which should, and could, be prevented. The formation of a medical union by the Leicester practitioners and the discussions in the medical and local press concerning the grievances of medical men have awakened the attention of the board which manages the Leicester Infirmary. This proves the utility of organisation and of agitation. In interviewing various medical men at Leicester I was much impressed by the difference of the tone of those who had not been to the infirmary for some years and of those who were actually on the visiting staff. Thus a former member of the visiting staff told me that he had seen and prescribed for some 17,000 patients at the infirmary. Many of these patients could well have afforded to pay a medical attendant. He remembered notably the wife of a tradesman who was in a large way of business. He remonstrated with her for coming to the hospital, but she replied that the gentleman who had subscribed two guineas to the hospital and had given her a letter of recommendation had the right to send whom he liked. It seemed to her preposterous that the medical man should interfere and ask questions when the gentleman who had given two guineas had asked no questions at all; and what business had the medical men to interfere with so reasonable and fair a bargain? That the members of the honorary staff of a hospital are by reason of their gratuitous services donors of what is equivalent to far more than two guineas is not realised by many persons; indeed, any number of patients imagine that the medical staff at the hospitals are paid, and handsomely paid, for their work. Thus the patient in effect says to the medical man: "The gentleman who gave me this recommendation has paid you two guineas to attend to me, therefore why do you ask impertinent or inquisitorial questions before giving me the advice and the medicine I need." It is quite a revelation to such persons to hear that the medical man has not been paid at all and only consents to work gratuitously on the express condition that his services shall be considered as a deed of charity done for the exclusive benefit of the poor, who are not in a position to pay. To make matters worse, the person in question was a member of a club and only paid 4*s.* 4*d.* a year for medical attendance; yet when she wanted a second opinion she came to the infirmary so as to get that second opinion for nothing. There were hundreds of other tradesmen and people well enough off not to need the charitable services either of a club or hospital medical officer who flocked to the infirmary. Also the impression that the members of the infirmary staff are well paid for their services engenders the idea that they must be very rich and would therefore charge their private patients very high fees; consequently the patients try to see them at the infirmary, where there is nothing to pay.

Some eight or ten years ago the infirmary physician who gave me this information brought before the board of management some flagrant cases of abuse. He was, however, rebuked and told that it was not his business to inquire into the status of the patients. He mentioned, among other such cases of abuse, that of the son of a person who was earning about £500 a year and yet sent his son to the infirmary. The boy was suffering from typhoid fever. The son of another well-to-do professional man was likewise taken to the infirmary. Then there had been a notable change in the behaviour of the large county families in regard to their servants. Formerly the nobility and the landed gentry always sent for their family medical man to attend their servants, but of late years the people who have bought many of the estates that used to belong to the ancient families find that it is at once cheaper and much less trouble to subscribe to the infirmary and send their servants there when ill. Like their predecessors they give to the charities; but unlike their predecessors they make the utmost use of these charities. Unfortunately, this example has been followed by some of the older families; thus the custom introduced by the newcomers proves doubly disadvantageous to the medical profession.

There has, however, been some awakening of late, and the infirmary board now feels that efforts must be made to prevent abuse. The rule is that all subscribers of two guineas annually are governors of the infirmary during payment and may recommend two in-patients and four out-patients every year. Those who subscribe one guinea can recommend one in-patient and two out-patients. There is, however, a rule that "no patient can be admitted who is able to pay for medical treatment," and Rule 72 states: "Persons who are able to pay for medical or surgical treatment are disqualified for admission to the infirmary. If any person recommended for admission shall appear to the physician or surgeon admitting patients to be clearly disqualified under this rule, the physician or surgeon shall report the case to the weekly board for their decision." This is a distinct improvement on the attitude of the old board, which some years ago told a member of the staff that it was not his business to inquire into the status of the patients. Nevertheless, through carelessness, if through no other reason, hospital abuse still prevails. Thus the other day a lady was admitted for an important operation. A fee of £100 might have been charged for this operation, and as the lady's husband is well off there is no reason why this fee should not have been paid. Nevertheless, the operation was performed gratuitously at the infirmary. Then two other quite recent cases were mentioned to me. The patients were together in the same ward. One of them was the wife of the owner of a large business, and the father of the other patient was earning £300 a year. Nevertheless the ticket of recommendation by which such patients gain admission contains the following declaration which the subscriber must sign: "The circumstances have been carefully enquired into, and I believe it to be a suitable case for admission for an in-patient." A similar declaration is signed on the recommendation paper for out-patients; yet the impression prevails that the abuse is even greater in the out-patient department than among the in-patients. Nor is this altogether the fault of the subscribers. Undoubtedly they are very careless in distributing recommendations, but no instructions are given as to what constitutes an abuse of the hospital, and each subscriber is left to define abuse according to his own particular fancy or ideas. There is no wage limit whatsoever; there is not even a hint given as to what might possibly constitute a fair wage limit. The bulk of the subscribers know little or nothing concerning the economic position of the medical profession and how it is affected by hospital abuse; therefore they often sign the declaration quoted above without making any inquiry worthy of the name. Hence the whole burden of preventing abuse falls on the medical staff, and it is scarcely necessary to repeat yet once again that this is in no way their business. It forms no part of a medical man's education to be able to detect what are the financial means of hospital patients. Nor is it fair to call upon him to render himself unpopular in the town by asking inquisitive questions which have nothing to do with medical treatment. This work should be done by a disinterested officer specially appointed for that purpose by the infirmary board. An efficient inspector could probably be obtained for a salary of about £75. This outlay would be more than compensated by the economy realised in reducing the total number of patients treated, as many persons who can afford to pay private medical practitioners would thus be kept away.

The number of patients treated at the Leicester Infirmary in 1896 amounted to 16,941, of whom 2892 were in-patients. This is practically the same as in the previous

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; and (9) May 8th, 1897, France, United Action and Legislative Action.

Hosted by Google

year. The daily average number of in-patients was 190, and their average treatment amounted to twenty-four days, the cost being 19*s.* 1½*d.* per week, or £3 5*s.* 7½*d.* for each patient. The income from all sources was £10,921 15*s.* 3*d.*, as compared with £11,075 4*s.* 10*d.* for the year 1895. A difference of £593 in legacies is the principal cause of this decrease. But what deserves especial notice is that the annual subscriptions only amounted to £2649 9*s.* 6*d.*, showing an increase on the previous year of £109 9*s.* 6*d.*, whereas the donations from the workpeople amounted to £3187 2*s.* 9*d.* and showed an increase of £320 13*s.* 11*d.* The last annual report says that "this is the largest sum ever yet received in one year from this source, and it is most gratifying to observe the generous support given to the infirmary by those for whose benefit it is maintained." Of course, in one sense this is very satisfactory, but the medical men at Leicester, as elsewhere, are beginning to feel its inconvenience. More than once I heard the familiar complaint that workpeople had claimed to be treated at the infirmary as a matter of right because they subscribed. The hospital is governed by a general board of governors, which meets four times a year, and by a weekly board and council. Now "every congregation, society, or association of persons (and these words shall include the employés of mercantile or other establishments) which shall have contributed the sum of five guineas or upwards in two or more successive years, shall have the privilege of nominating one person, being a member of such congregation, society, or association, to act as a governor in respect of such contribution, after the second year's payment, and to continue as such governor for one year." Thus workmen must subscribe five guineas to appoint a governor, whereas middle-class men can constitute themselves governors by paying only two guineas. It is difficult to see on what logical grounds this fancy franchise can be maintained. If money is to be the basis of representation the workmen might well claim that the qualification should be raised to five guineas all round or else lowered to two guineas. This claim they could easily enforce by simply refusing to pay in their £3000 till it had been admitted. What then would be the position of the infirmary? On the two-guinea franchise basis the workpeople could nominate about 1500 governors, while the annual subscribers—admitting that those who give less than two guineas took the trouble to club together so as to appoint governors—could only appoint about 1300 governors. But such combination is not likely to be effective, for the greater part of the annual subscribers are notoriously supine in such matters. Then there are fifty-seven life governors, and the collections last year amounted to £1354. Even if every penny given was utilised in acquiring the franchise still it will be seen that the workmen governors would constitute a very large minority, if not an actual majority. Also it is quite possible that many of the governors who were not direct representatives of the working classes might vote in favour of the proposals brought forward by the working classes. Thus we are brought face to face with the possibility of the working classes becoming the masters of the infirmary. It will be of no use dealing with this question when this end is realised. Its occurrence can only be prevented if the question is taken up in time, and it is perhaps already too late. The workmen do not yet fully realise their strength and have not given very much attention to the subject; but the matter has been taken up by the Leicester Trades Council, and one of the best-known physicians in the town, in mentioning this fact, expressed his opinion that they were going straight towards the municipalisation of the infirmary. There is consequently no time to lose. The probable effect of the working-class support now so largely given to hospitals must be faced.

THE CONGRESS OF THE GERMAN SURGICAL ASSOCIATION.

(FROM OUR BERLIN CORRESPONDENT.)

(Concluded from p. 1306.)

Acute Intestinal Obstruction.

PROFESSOR HEIDENHAIN of Greifswald read a paper on the Pathology and Treatment of Acute Intestinal Obstruction. He said that intestinal spasm was sometimes due to abnormal conditions in some part of the bowel, such as stricture of the rectum, ascarides, &c., and might sometimes be caused by impaction of a testicle in the inguinal canal or by twisting of the pedicle of an ovarian cyst. The effect in these cases is brought about by reflex action, and the symptoms may, of course, be removed by appropriate remedial measures. Incomplete stenosis arising from chronic peritonitis is also sometimes successfully treated by irrigation of the stomach. The same may happen when the intestine is obstructed by a gall-stone and in invagination or incomplete volvulus. But in many instances the symptoms recur, and the patient may die after repeated attacks of ileus. Operation should therefore be the rule. Professor Heidenhain suggested that before the obstacle is sought for an incision should be made into the distended intestine in order to remove its contents, as he is of opinion that the severe symptoms in acute obstruction are not due to primary peritonitis, but to toxic effects of virulent substances produced in the stagnant contents of the bowel. After the intestinal incision has been closed by sutures the search for the obstacle may be commenced, and for this purpose it will be necessary to withdraw the bowel to some extent from the abdominal cavity. After the operation castor oil should be administered; it generally causes very fetid motions, and the patients, as a rule, feel very much relieved. In this way it is possible to prevent peritonitis, which, in Professor Heidenhain's opinion, is caused by the immigration of pathogenic bacteria through the intestinal walls into the peritoneal cavity.

Puncture of the Spinal Canal.

Professor Braun of Göttingen read a paper on Puncture of the Spinal Canal. In suppurative meningitis following otitis media or traumatic lesion of the skull he found the fluid in two out of eight cases to be completely limpid, so that suppurative meningitis is not negatived by the absence of pus from the fluid. The increase of leucocytes is, however, very important from a diagnostic point of view. If blood is obtained from the puncture compression of the medulla is very likely to be present, and by the withdrawal of the blood the compression is relieved. Professor Braun argued that puncture of the spinal canal is valuable as a means both of diagnosis and of treatment, and that though it has hitherto been used almost exclusively in medical cases, it is, nevertheless, applicable in surgical practice as well.

Collective Investigation on Anæsthetics.

Professor Gurlt, the secretary of the association, gave an account of the collective investigation on anæsthetics begun by the Association in 1891 and continued ever since. The returns comprised two years—1895, with 19,596, and 1896, with 23,173, cases. Of this number chloroform was given 27,025 times, with 29 deaths, and ether 19,856 times, with 3 deaths. On the other hand, there was no death among 996 cases of anæsthesia produced by Billroth's mixture, 4927 by a mixture of ether and chloroform, and 1489 by bromide of ethylene. When all the 327,500 cases recorded since 1891 are summarised, the general death-rate is 1 in 2444, and that for each of the anæsthetics is as follows:—Chloroform, 1 in 2039; ether, 1 in 5090; Billroth's mixture, 1 in 3807; bromide of ethylene, 1 in 5228; chloroform and ether mixture, 1 in 7594, and pental 1 in 213. The latter anæsthetic no longer appears in the returns and therefore seems to be abandoned. In the first three years no death from ether was recorded; afterwards its death-rate varied from 1 in 2300 to 1 in 6700, and that of chloroform from 1 in 1100 to 1 in 4200. It was decided to continue the collective investigation, and the thanks of the association were given to Professor Gurlt for his work.

Laryngeal Carcinoma.

Dr. Graf of Berlin discussed the Results of Operations for Laryngeal Carcinoma performed in Professor von Bergmann's clinic. From 1883 to 1896 there were forty-eight cases operated on, of which forty-seven were carcinoma and one was malignant enchondroma. Tracheotomy was always performed first, Hahn's cannula was inserted into the tracheal wound, the larynx was then opened in order to ascertain the extent of the growth, and after the extirpation sutures were applied. An artificial larynx was used in only seven cases. Of the patients with total extirpation two have been free from recurrence for seven and three years respectively; four patients with unilateral extirpation and four with partial extirpation are still alive.

Pharyngeal Carcinoma.

Professor Krönlein of Zürich then delivered an address on

Hosted by Google

Pharyngeal Carcinoma, a condition which, in his experience, is not so rare as is usually believed. He has seen in Zürich sixty-one cases, of which fifty-six occurred in males and five in females. He classified the growths according to their localisation, as naso-pharyngeal, oro-pharyngeal, and laryngo-pharyngeal. The first are very rare, but instances of the second and third kind are more frequently observed. Naso-pharyngeal carcinoma has not yet been operated on. Of the oro-pharyngeal cases he has operated on fifteen with few relapses; of the eight laryngo-pharyngeal cases six died from the operation, one from a relapse, and only one survives. Of all the sixty-one cases of pharyngeal carcinoma, twenty-nine only were operable, eleven died from the operation, two were cured, and the others died from relapses.

Considerations of space permit only a passing reference to other papers read at the Congress, the principal of them being those by Dr. Koerte on the Surgical Treatment of Diffuse Peritonitis, Dr. Marwedell (Heidelberg) on the Value of the Murphy Button, Dr. Sonnenburg on Operations for Rectal Stricture, Professor Kuster (Marburg) on Fibrous Ostitis, Dr. Bencke on Gonorrhœal Arthritis, and Dr. Halbau (Vienna) on the Absorption of Bacteria.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Ingleby Lectures.

THE President and Council of Mason College have issued cards of invitation for the Ingleby lectures for the present year, which are to be given on Wednesdays, May 19th and 26th, by Mr. Bennett May, the subject being the Operative Treatment of Cancer of the Breast.

Hospital Reform.

The Birmingham Trades Council have expressed their opinion strongly on this vexed subject. The following resolution was proposed at a recent meeting of the body: "That this council respectfully declines to accept the view expressed at the meeting lately held, and is of opinion that all cases of injury caused by accident and requiring medical or surgical treatment should be admitted without demur. Further, this council protests against the practice of men and women being called upon to pay the shilling fee if they have occasion to attend the hospital for medical aid or advice when they are already paying weekly subscriptions through their factories and workshops for the same institutions." It was stated by subsequent speakers that the resolution was a protest against the statements made at a meeting of the Hospital Reform Association. The question, it was averred, was, Were the hospitals merely to treat cases approved by the medical officers or were the subscribers to the Hospital Saturday Fund to be entitled to first aid? The chairman said that the discussion tended to show that the hospitals were not the institutions people thought they were. They had been taught to believe that they were charitable institutions, but it had been proved that a man who paid a penny a week could practically demand treatment for nothing, whereas a man who did not pay to a hospital direct could not have direct treatment. If that were true it destroyed the whole idea of hospitals as charities. He did not see why a man who earned £100 a week if he paid to the hospital was not as equally entitled to treatment as the man who earned £1 a week. Such and similar opinions expressed by a representative body of workmen go to show the trend of public opinion in the present day on hospital administration questions.

Accident at the New General Hospital.

A lamentable accident happened on the 3rd inst. to Mr. Philip Osler, aged twenty-one years, which resulted in his death in a short time. Mr. Osler was engaged in testing the electrical communications, and it is supposed that during an interval in this duty he attempted to pass through a trap-door on to the roof of the building. Below the door, which is reached by a small ladder, is a glass skylight window, through which Mr. Osler fell, and was found on the floor beneath in an unconscious condition. He was at once taken to the Birmingham General Hospital where it was found that his skull was fractured and where he soon expired. Mr. Osler was a young man of exceptional ability and promise, and his death cast a gloom upon the staff engaged on the building. Much sympathy has been expressed with his parents in this sad calamity.

Midland Counties Idiot Asylum.

Lord Leigh, chairman of the committee, moved the adoption of the thirtieth annual report at a meeting of this institution held on the 5th inst. at Walsall. It was shown that the total expenditure for 1896 was £1954 1*s.* 9*d.* and that there was an adverse balance of £144 19*s.* 8*d.* The progress had been satisfactory and the amount of good done very great. It was pointed out that the founder of the institution was Dr. Bell Fletcher, one of the physicians for many years to the Birmingham General Hospital. Dr. Fletcher is still living at Leamington, having attained to the great age of nearly ninety years.

Birmingham.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Difficulties of the Rivers Committee.

AT the meeting of the City Council on May 5th the Rivers Committee asked the council to sanction the expenditure of a large sum for the building of two additional filtration tanks of an acre each in extent for the purpose of testing a system of filtration recommended by Sir Henry Roscoe on a much larger scale than had hitherto been possible. Councillor Bradley objected that neither the filters nor the experiments were necessary, and the matter was referred back to the committee for further consideration. This leaves matters much as they were, for it may be remembered that the culvert scheme for taking the sewage effluent from Davyhulme to the estuary of the Mersey was rejected by a town's meeting. It will be necessary to arrange something before long, as the council will have to appear before the stipendiary magistrate in September with a complete scheme of sewage treatment in obedience to an order of the court, in default of which the corporation will be liable to heavy daily penalties.

Muzzling v. Registration of Dogs.

At a recent meeting of the City Council, Alderman Mark stated that the present muzzling order existing in Manchester was made by the local authority on Feb 20th, 1895. After a period of fifteen months it was decided to try the alternative of "registration with name and address, collars, and a brass badge," and this came into effect on June 1st, 1896. During the fifteen months fourteen dogs had been captured reported as suffering from rabies, while, during the eleven months of registration five cases had occurred, but the report as to the last case had not yet been received. The Watch Committee had registered for this year 7088 dogs, and if the new muzzling order were issued it would put the committee in a difficulty with 7088 owners. A deputation introduced by Sir W. H. Houldsworth laid the matter before the President of the Board of Agriculture, who admitted that there was a strong case for their application that the local regulations might be allowed at any rate to exist for the present and that the contracts should be allowed to lapse by the efluxion of time. The final answer to their request had not yet been received. In the meantime orders had been given to the police to be more active than hitherto in the capture of vagrant dogs.

Insanitary Cowsheds.

The medical officer of health has issued an important report on the Manchester cowsheds. Powers have been given to the City Council to deal with the matter, and the Sanitary Committee is seeking to enforce these powers, and to compel cow-keepers to keep their sheds clean. The cows in the city it appears are largely affected with tuberculosis.

Manchester Medical Cricket Club.

The fifth annual general meeting of this club was held at 98, Mosley-street, on the 6th inst. The honorary secretaries' report stated that the number of members was exactly 100—twenty-seven being life and seventy-three ordinary—members, consisting of both medical men and students. Seven matches had been played during the last season, of which two—Liverpool Medicals and the Law—had been won, those against Cheadle and Prestwich Asylums and Worsley drawn, and one lost—that against Heywood. The honorary treasurer's report was favourable, showing several pounds to their credit at the bank, although

Hosted by Google

many members had forgotten to send in their subscriptions, which omission can easily be rectified when they see this notice. It was decided that about six definite fixtures should be made for the coming season—Past *v.* Present Students, Liverpool Medicals, Cheadle Asylum, Clergy, Law, and Prestwich Asylum. Other matches will probably be played as occasions offer, such as Married *v.* Single, Veterans *v.* Novices, Town *v.* Country, &c. It was felt that if medical men and students were only made aware of how pleasant these *réunions* are many would avail themselves of being enrolled members, which only entails an annual tax of 2*s.* 6*d.* It was resolved unanimously to abolish the rule as to the election of any further life members. The president of the club has promised to present a bat for the best batting average in four matches, one vice-president a ball for the best bowling average, and the other vice-president one for the best all-round man, batting and fielding. The following office-bearers were unanimously elected for the ensuing season:—President: T. Harris. Vice-Presidents: G. H. Broadbent and W. Scowcroft. Committee: E. M. Ashcroft, J. Bradley, H. H. Hitchon, C. Iliffe, A. Lomas, and T. Rothwell. Hon. Treasurer: H. W. Boddy, Cheetham-hill. Hon. Secretaries: G. W. Beesley, 226, Lower Broughton-road, Salford, and T. L. Fennell.

May 11th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Workhouse, Newcastle-on-Tyne.

OWING to the rapid increase of the population of Newcastle the present accommodation at the workhouse has become inadequate, and the question of increasing the size of the present building is under the consideration of the guardians. Mr. Gordon Smith, architect to the Local Government Board, told the guardians at their last meeting that the present buildings were obsolete. He further pointed out that in any re-arrangement of the building it would be necessary that the infirmary should be kept separate from the workhouse proper, and that the children must be provided for in a distinct building. After discussion the three following questions were raised for further consideration: (1) Should the children be removed from the workhouse; (2) should the present building be extended; and (3) should the site be changed.

Election of Assistant Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

On May 6th Dr. John Rutherford was elected an honorary assistant surgeon in place of Mr. Rutherford Morison, who lately succeeded to the post vacant by the retirement of Professor Arnison. There were five candidates for the assistant surgeoncy.

Increase of the Salary of the Medical Officer of Health of the County of Durham.

Dr. T. E. Hill, the medical officer of health of the county of Durham, has had his salary increased from £500 to £700 a year on the recommendation of the health committee of the Durham County Council.

Complimentary Dinner to Professor Arnison.

On the evening of May 7th a dinner was given to Professor Arnison by his colleagues on his retirement from the post of surgeon to the Royal Infirmary, Newcastle-on-Tyne. Dr. Hume occupied the chair, and during the evening proposed Professor Arnison's health, alluding in kindly terms to his long and honourable connexion with the infirmary, and expressing the feelings of all his colleagues for Professor Arnison's future welfare.

Grange over-Sands Convalescent Home.

This institution, promoted by the Friendly Societies of Northumberland and Durham on the suggestion of Dr. William Robinson of Sunderland, has just been declared open by Sir James Laing. It is likely to be an immense boon to the north of England.

Lieutenant-Colonel Jeaffreson.

Dr. C. Jeaffreson, the well-known Newcastle ophthalmic surgeon, has been granted the honorary rank of Lieutenant-Colonel in the 3rd V.B. Northumberland Fusiliers, in which corps he had served as a combatant officer since 1878. He will also receive the Volunteer decoration for twenty years' service, having joined the Birmingham Rifles as an officer in 1866.

May 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

ON Tuesday of last week Sir Henry Littlejohn delivered his opening lecture as Professor of Forensic Medicine in the University of Edinburgh, before a crowded audience of students and members of the medical faculty. The new Professor was introduced by Principal Sir William Muir, who at the same time expressed his sense of the loss sustained by the University in the retirement of Sir Douglas Maclagan. Sir Henry Littlejohn, who was enthusiastically received, then delivered his opening lecture. He referred to the reception given him as a sign that he required no introduction to the students of that medical school with which he had been connected for forty years. In the large number of extra mural lecturers working in connection with it, the University had an important adjunct. With that number he had been closely connected, and he felt that, while within the precincts of the University there might be a "purer ether, a diviner air," his intercourse with young and enthusiastic workers in the extra-mural school had been an admirable training for the duties of a professor in the University. He then explained the lines he intended to follow in conducting his lectures, and pointed out the great necessity for teaching the subject of forensic medicine in a practical manner. In his capacity of surgeon to the police he would constantly have cases under his notice which he would consider it his duty to discuss with his students, and he also would wish them occasionally to attend criminal trials in the Court of Justice. Sir Henry Littlejohn went on to allude to his predecessors in the chair—to Dr. Duncan, the first Professor of Medical Jurisprudence in the United Kingdom, and to Sir Robert Christison, described by Orfila as "the leading medical jurist of the day." His immediate predecessor he referred to last, speaking in high terms of the character and attainments of Sir Douglas Maclagan, who, he said, reminded one of the days of Arbuthnot, Armstrong, Pitcairn, and Radcliffe. He was a man who had conversed familiarly with Goethe, been the friend of Lord Macaulay, and had seen Sir Walter Scott, while he had held the position of President of the Royal Society, of the Royal College of Surgeons, and of the Royal College of Physicians. Sir Henry Littlejohn concluded by stating his intention of walking in the footsteps of Sir Douglas Maclagan, and of placing at the disposal of the University whatever advantages his official position in the City might give him in the conduct of the chair, while he would endeavour to communicate to his students the enthusiasm with which he himself had prosecuted the study of the science.

Glasgow Medical Societies.

THE meeting of the Glasgow Medico-Chirurgical Society on the 7th inst. was presided over by Dr. Walker Downie. Dr. Barr showed a fresh specimen from a case of Cerebellar Abscess. The specimen included the brain and the temporal bone and was of special interest as illustrating how in middle-ear disease the path by which extension to the brain occurs may be through the labyrinth and the internal auditory meatus. Dr. Edington showed a girl, aged eight years, on whom excision of the Scapula for Sarcoma was performed four months ago. The tumour was shown to involve the infra-spinatus muscle, whilst the bone itself was unaffected. It was pointed out that this fact and the large proportion of spindle cells of which the tumour consisted made the outlook with regard to the prospect of recurrence comparatively good. Mr. Clark and Dr. Dalziel expressed their agreement with the procedure adopted and related particulars of similar cases. Dr. Barr and Dr. J. H. Nicoll read a communication on a case of Cerebral Tumour and showed the specimen. The patient, a young lad, first came under observation with what looked like a simple polypus of the external auditory meatus. This was removed, but recurred on two occasions. Subsequently the boy developed symptoms which suggested cerebral abscess, but on opening the skull a tumour was found. This was removed as far as possible, and the boy lived for two and a half months, but then died. The tumour, both in its macroscopic and microscopic characters, presented features which led to much difference of opinion as to its nature; and whilst Dr. Barr suggested that the intra-cranial tumour was an extension from a growth

Hosted by Google

in the middle ear, others were inclined to regard the intracranial growth as the primary event. Another feature of interest was that the patient when under chloroform passed into a condition of apnœa, for which artificial respiration was required for a prolonged period, the breathing, however, becoming at once re-established when the skull was opened.—The Pathological and Clinical Society held a meeting on the 10th inst., the chair being taken by Dr. W. J. Fleming. Professor Gairdner read notes of a case of Mitral Stenosis and showed the Heart. The patient was a young woman, who complained of hæmoptysis and who on physical examination showed a typical auricular-systolic murmur. After some months in hospital, during which time there were periods of high fever and signs of pulmonary disease, suggesting phthisis pulmonalis she died, but a few days before death the auricular-systolic murmur disappeared and a soft blowing ventricular-systolic murmur developed. The post-mortem examination showed a narrowed mitral orifice, and on the anterior curtain of the valve was a large thrombus of recent date, and the suggestion was that it was the development of this thrombus which was the cause of the appearance of the systolic murmur. Professor Gairdner also read a communication on the subject of Thoracic Aneurysm. He showed a number of preparations to illustrate how such aneurysms may press upon, and even open into, the vena cava superior, the pulmonary artery, or one of the cavities of the heart. Professor Gairdner commented upon the facts demonstrated by the specimens, and connected these with the clinical histories for the purpose especially of arriving if possible at definite conclusions in view of the diagnostic difficulties of the cases. More particularly he alluded to the auscultatory signs to be expected when a communication is established between an aneurysm and a neighbouring vein.—Dr. Hector Cameron showed a man in whom he had Ligatured the First Part of the Axillary Artery in consequence of the existence of an aneurysm in the third part of the subclavian artery. The case had been quite successful, but some weeks after the operation the patient became hemiplegic on the right side. From this, however, he had now recovered.—Dr. W. L. Reid showed a case of Hæmatosalpinx, and Dr. L. R. Sutherland reported on the case.

May 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland.

THE annual election of the Court of Examiners of the College took place on the 4th inst., when with few exceptions the same gentlemen who filled the office last year were re-elected. Dr. R. Glasgow Patteson of the Meath Hospital was, however, elected for the first time an examiner in surgery.

Mercer's Hospital, Dublin.

A special meeting of the Board of Mercer's Hospital is called for Tuesday next, May 18th, 1897, to elect a new medical staff, the services of the old staff having been dispensed with.

The Longford Board of Guardians.

According to a statement in the *Freeman's Journal* of May 5th Dr. Robert Cochrane of Longford has recently served a writ for £500 on one of the Longford guardians, who had accused him of having left a patient until he was in a dying state and then ordered him to be removed in the inefficient workhouse ambulance.

Urban Sanitary Districts around Dublin.

Mr. T. J. Stafford, medical inspector of the Local Government Board, held an inquiry on the 4th inst. in the board-room of the South Dublin Union in connexion with an application of the guardians of the union to be constituted an urban sanitary authority for the electoral divisions of Rathfarnham and Palmerstown. The minutes of the inquiry have been laid before the Local Government Board, who have not communicated their decision on the matter.

The Medical Benevolent Society.

The annual meeting of the Belfast branch of this society was held on May 5th, the President of Queen's College occupying the chair. In the report it was mentioned that the subscriptions have increased this year. Special reference was made to the loss sustained by the society by the death of Mr. F. E. Beck, who had been for twelve years treasurer. The following office-bearers were elected for the ensuing year: President, Dr. Whitaker; Secretary, Dr. M'Caw; Treasurer, Dr. R. J. Purdon; Committee: Professor Cuming, Professor Whitla, Professor Byers, Mr. Payne J P., Dr. Brice Smyth, Dr. Merrick, Mr. McDonnell, J.P. (Randalstown), Dr. M'Keown, Dr. James Graham, Dr. Gibson, Dr. Bolton, J P. (Bangor), Mr. James Smith, Mr. M'Connell, Dr. H. O'Neill, Dr. Gaussen (Dunmurry), and Dr. Munn.

Queen's College, Belfast.

The following is the prize list in the class examinations of the medical faculty at the close of the winter session, 1896-97:—Systematic Anatomy—Seniors: Robert Alister Little Graham, B.A., and John Edmund Clements. Juniors: John Elder MacIlwaine, Hugh Barkley Steen, and John Hope Reford, B.A. Practical Anatomy—Third Year: William Matthew Hunter. Second Year: Robert Alister Little Graham, B.A., and Galbraith Hamilton Grills, equal; and John Elder MacIlwaine. First Year: Samuel M'Clure and John Alexander Douglas Radcliffe. Physiology and Histology—Senior Division: William Matthew Hunter. Junior Division: David M'Mordie, John Campbell Rankin, and Archibald George Heron. Practical Physiology and Histology: David M'Mordie and Howard Stevenson. Surgery—Second Year: Arthur Berry M'Master and George Adams Hicks, equal; Charles Edmund M'Dade, B.A. First Year: Henry Stewart Anderson, George Jefferson. Materia Medica: Robert Alister Little Graham, B.A.; William Matthew Hunter. Midwifery, Gynæcology, and Diseases of Children: Arthur Berry M'Master, Henry Stewart Anderson, and William Boyd. Practical Chemistry—Senior Division: Wm. Alexander Stoops. Junior Division: Robert George Campbell. Zoology—Senior: David M'Mordie. Junior: Walter Phillips, Charles James Ross, B.A., Frederick William Stewart, and John Armstrong. Ophthalmology and Otology: George Adams Hicks, George Casement Reid Harbinson, and Charles Edmund M'Dade, B.A. Sanitary Science: George Adams Hicks and George Casement Reid Harbinson.

The Belfast Asylum.

It was reported at the last meeting of the governors, held on May 10th, that a scheme has been arranged by the architect which would be sufficient to complete and perfect the purification works at Purdysburn so as to secure a clear and pure effluent from the sewage system. This discharge will not flow into the Purdysburn River (to which the adjacent inhabitants objected), but will be absorbed by the land. This scheme was passed, although Dr. O'Neill (one of the governors) thought it was complicated and that a simpler plan which he had seen in use in London would have done—that is, passing the effluent through coke before entering the river. The object of the architect's plan is to protect the interests of the inhabitants of the district around the new asylum. Dissatisfaction was expressed at the action of the Board of Control in Dublin in accepting a tender for the erection of a new gate lodge without having in the first instance (as is usual) sent the tenders to the board of governors in Belfast for their consideration.

May 11th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Fire at the Charity Bazaar.

IN the lamentable catastrophe of May 4th no less than 170 persons were killed and the number of the injured is as yet unknown, although it is probably about 300. The burns are of two kinds—those produced directly by contact with burning draperies or clothing or the drops of flaming tar which fell from the roof, and those due entirely to scorching from the excessive heat which penetrated through the clothing. Most of the injured show large burns on the back and limbs, burns of the second degree, produced by radiation through the clothes, although the clothes themselves are unharmed. Many deaths have occurred from pneumonia following the inspiration of superheated air, and others have died from the pneumonia so often observed to follow extensive burns under any circumstances. The number of those showing more or less defined mental disturbances is very considerable; some, for instance, cannot bear to be in an enclosed or crowded place—for instance, a full church—

Hosted by Google

without being seized with a nervous crisis. Some of these sufferers exhibit definite injuries other than burns—namely, bruises, fractures, marks of blows from fists or sticks received in the panic-stricken rush to the doors in which some 1400 people managed to escape by two narrow doors in about seven minutes. As to the dead, all the bodies show injuries to the head, probably caused by the fall of the flaming tarred roof, and to this and the strength of the masculine hat is perhaps due the fact that of 150 bodies only 3 were those of males. The bodies presented a heart-rending spectacle: the head was either completely destroyed or in some cases only as far as the base of the skull or the teeth, the cranial cavity was laid open either by the excessive heat having scorched the bones or from the burning tar having calcined them so that they crumbled at the first shake upon moving the body. This latter theory is probably the correct one, for in many cases the brain lay by the side of the body, fresh, pink, and barely touched by fire. The abdomen in some cases was burst open by the pressure of heated gas; in nearly all the hands had disappeared and in many the very arms themselves; the feet, with their coverings, were in most cases untouched. The recognition of the bodies by their relatives was most difficult, and could only be carried out in most instances by peculiarities of dentition, and in a certain number of bodies any identification was impossible. The medical men of Paris have suffered severely by this catastrophe; two of the stalls were presided over by the wives of Dr. Péan and Dr. Feulard, and many ladies connected with the medical world were assisting them. Among the dead is Dr. Feulard himself. He had managed to get out with his wife, who was only slightly burned, but went back to look for his daughter who had been unable to follow them and was crushed by the fall of the burning roof. Dr. Feulard was a noted dermatologist, quite young, and physician to the hospital of St. Lazare. He was the organiser of the magnificent dermatological collection in the museum of the hospital of St. Louis. Another medical man among the dead was Dr. Rochet, a homœopath. Among the women who were killed were the wife and daughter of Dr. Nitot, the sister of M. Picquet the surgeon, the mother and wife of Dr. Vimont, the daughter of Dr. Simon, the daughter of Dr. Le Sourd, and the sister and niece of M. Nélaton, and many other wives of medical men were burned more or less severely.

The Recent Trial for Abortion.

The Court of Cassation has rejected the appeal of the two defendants in the recent abortion case, and has confirmed the sentence passed by the Court of Assize, a decision which has greatly astonished the medical men of Paris, who knew the numerous irregularities in the process of indictment, and how certain witnesses favourable to the accused had been prevented from giving evidence. Dr. Boisleux has gone out of his mind and has been transferred from prison to an asylum.

The Medical Associations.

There are in Paris two medical associations; to the older one belong the greater part of the medical men of the capital, and its president is the Dean of the Faculty. Its title is, "The Association of Medical Men of the Seine," but within the last four years some of the members have founded another association under the somewhat similar title of "The General Association of the Medical Men of Paris, and the Department of the Seine." The split arose upon the question of "clinics," which the older association considered should be paying institutions, but which the younger body thought should be free to open gratuitously or to demand payment at the will of the medical man in charge. The new association comprises all those specialists who are the owners of clinics, which they conduct without payment, particularly at the International Hospital, where they are at the head of affairs. A bitter newspaper war has been going on for the last four years between the two associations, all the more bitter because the members of the new association have not ceased to belong to the old one, and claim the right to be present at the meetings, and to propose revolutionary motions, and so the old association has just decided to demand the resignation of these members. But this course of action is surrounded with difficulties. The laws of the association are modelled upon those of workmen's associations which were drawn up to prevent a minority being tyrannised over by a despotic majority, which would naturally wish to free itself from hostile members by the method of expulsion. Therefore, as the law stands, no member of an association can be expelled except by the unanimous vote of the rest, unless under very exceptional circumstances, such as being a convicted felon. It has frequently happened that workmen's clubs have wished to expel the minority, and every time they have been fined and had to pay damages. Therefore, as the general law of associations governs the medical bodies it follows that the expulsion of the members of the new association would be illegal. The debate on the subject was very heated, many members tried in vain to get a hearing and bring about a reconciliation, but the majority of the old association gave a vote that after the lapse of a month the members of the new association should be considered as dismissed. It is reported that the expelled members are going to bring the matter into court.

The Medical Congress.

The annual meeting of the Ophthalmological Society and the Society of Laryngology, Otology, and Rhinology takes place this week. In the last department M. Castex read a remarkable paper on some cases from a medico-legal point of view—a subject which has received but little attention, but which is, nevertheless, important. The sittings of the Society of Ophthalmology were disturbed by the professional discussions which come up every year as to the "clinic" at the hospital of the Quinze-Vingt (Blind). This hospital was founded twenty years ago by Gambetta as an office for his friend Fienzal, and it has since become little by little an establishment under official protection to which come patients from all parts of France, both rich and poor, their expenses being defrayed by their commune. The ophthalmic surgeons, especially those in the provinces, protest against this abuse, but the public is, of course, delighted to be treated gratuitously, and the Government dare not put a stop to the abuse for fear of losing the votes of the provincial deputy. The ophthalmic surgeons who are not on the staff wish the four who are to resign their posts by way of showing a true fraternal spirit. But it is more probable that they will continue to hold their position.

May 10th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Report of the German Commission on Plague.

THE German Commission on Plague in Bombay has issued a report which is dated March 19th, and has appeared in the *Deutsche Medicinische Wochenschrift*. Professor Gaffky acted temporarily as the head of the Commission until the arrival of Professor Koch from the Cape. It reached Bombay on March 8th and immediately began work in the Municipal Buildings, where a laboratory had been already provided by Dr. Bitter, the Egyptian Commissioner. There was some difficulty in obtaining an adequate supply of subjects owing partly to the religious prejudices of the natives against post-mortem examination and partly to the number of bodies taken by the Commissions of the various foreign nations; but by the courtesy of the authorities and of Dr. Bitter, a pupil of Professor Koch, arrangements satisfactory to the German Commission were eventually made. It was very soon found that the bubonic virus in the great majority of cases penetrated into the human body through small lesions of the skin. The glands of the neighbourhood then began to swell and, when the quantity of virus absorbed was not too large, they were able to retain and to destroy it. When the bacilli were present in large quantities they made their way through the lymphatic glands and were then found everywhere in the blood and in the internal organs. This was the typical form of bubonic septicæmia. When a gland suppurated the bacilli might be removed from the body, but a dangerous septicæmia caused by streptococci might result. The bubonic bacilli were present in large quantity in the patient's urine and fæces, and in this way the virus might become spread everywhere. In another group of cases the virus was apparently absorbed by the lungs, and under these circumstances primary pneumonia was commonly found, the lungs containing plague bacilli together with diplococci and streptococci. It is obvious how dangerous the sputum of such patients must necessarily be. Primary infection from the intestinal canal was not observed in any instance, but sometimes it appeared to arise from the tonsils. The low standard of living of the native population, their dirty habits, and their objection

Hosted by Google

to hospital treatment, were very favourable to the great spread of the epidemic, but the Europeans were almost entirely exempt. After the new Epidemic Diseases Act of 1897 came into operation the authorities took more active measures, and the special Commission under the presidency of General Gatacre displayed praiseworthy energy in providing for the compulsory removal of patients to the hospitals and for the isolation of suspicious cases in the so-called segregation camps. The report states that for the purposes of a bacteriological examination it was not sufficient to take a single drop of blood from the finger, as this method gave a satisfactory result only when the bacilli were present in very large quantity. An agar culture must be made in doubtful cases; the colonies were usually developed after forty-eight hours. The bubonic glands should not be punctured for diagnostic purposes, because of the risk of admitting the virus into the bloodvessels. The Commission found that if blood serum obtained from either persons or animals convalescent from plague was mixed in a test tube with a culture of plague bacilli it had a specific influence on them. Cultures of other bacteria treated in this way became opalescent throughout their whole extent, but the plague bacilli formed small coagula which, in course of time, fell to the bottom of the test-tube, leaving the supernatant fluid clear. This so-called "paralysis" of the bacilli was identical with that observed in the case of enteric fever and cholera, and led to the inference that artificial immunisation against plague might be possible, but the Commission has not yet finished its researches on this subject. The Commissioners state that they were unable to express a definite opinion as to the efficacy of the immunisation methods of M. Haffkine and Dr. Yersin.

ROME.

(FROM OUR OWN CORRESPONDENT.)

English-speaking Medical Practitioners in Italy.

A VERY grave measure threatens to become law in the Italian kingdom—grave as regards the English-speaking practitioner and not less grave as regards the English-speaking world. It is neither less nor more than the adoption by Italy of the exclusive legislation in which Switzerland led the way and France followed, so that no British qualification will entitle its holder to practise even among his compatriots resident on Italian soil. Yesterday in the Chamber of Deputies Dr. Santini, member for one of the electoral divisions of Rome, asked the Ministers of the Interior and of Public Instruction "if, in presence of the constant and increasing professional abuse on the part of foreign practitioners, while their Governments do not admit Italians practising abroad to reciprocity, but exact from them examination-tests and every other academic title without recognising those of Italy, their Excellencies do not think it time to modify Article 23 of the existing medical law?" Replying for the Government, Signor Serena said that a "modification in the medical law to regulate foreign practitioners exercising their profession in Italy will shortly be laid before the Chamber"—in other words, that the first step will be taken to assimilate Italian law to Swiss and French in regard to foreign practitioners. A movement in this direction has long been contemplated in Italy, but it was not till the close of last year that (as reported in THE LANCET, Dec. 19th, 1896, p. 1796) it took definite shape and course. Its promoters are not, as may well be supposed, recruited from the commercial, the railway, or the hotel-keeping interests—from the classes, that is, whose income so largely depends on the attraction of the English-speaking world to Italian soil—but (I am sorry to say) from the profession in Italy herself, represented by the "Consiglio dell' Ordine dei Medici." The innovation projected is not likely to become law without a stormy discussion first in the Chamber of Deputies and then in the higher atmosphere of the Senate, in both of which bodies there are statesmen enough to see and press home the folly of any legislation calculated to affect injuriously Italy's best customer and steadiest source of revenue. I shall keep THE LANCET informed of the progress of the measure through either House.

The Treatment of Tabes Dorsalis.

Mechanical intervention in this malady has lingered longer in continental than in British practice. Indeed, we have the high authority of Dr. W. R. Gowers for regarding suspension and nerve-stretching, "although recently fashionable," as "probably valueless." In Italy, however, the profession seems loth to resign all hope of effecting improvement at least by such or cognate means, and "flessione forzata delle gambe" (enforced flexion of the lower limbs) has rather been gaining than losing ground in treatment during the last few years. Recently adopted and recommended by the French, the Italian schools are claiming this practice as having originated with themselves, and the distinguished professor of psychiatry, neuro-pathology, and electro-therapeutics in the University of Genoa (Dr. Enrico Morselli) comes forward with an "apologia," in which the treatment itself and Italy's priority in devising it are strenuously vindicated. The following passage will interest your readers:—"Before this announcement of a 'French discovery' is repeated elsewhere, I hasten to put on record that the method alluded to is already quite familiar in Italy and, indeed, relatively old. From 1888 it was conceived and put in practice by my excellent friend Professor Bonuzzi of Verona, described by him and explained by illustrative figures in 1889, and slightly modified thereafter by Professor Benedikt of Vienna. There is no longer any neuropathologist who respects himself who has not adopted and practised it in place of the often useless and sometimes dangerous suspension. From 1892 I have practised and taught it here in Genoa in my clinique for nervous maladies, and this, not only in tabes dorsalis, but also in sciatica, in which at this very moment Professor Bonuzzi is demonstrating its advantages—advantages which I, too, have had the most recent occasion to confirm. I am waiting, indeed, till these are announced as a 'discovery' and vaunted as such by some non-Italian clinician."

Destruction of Captain Bóttego and his Column.

Yet another disaster to an Italian exploring expedition in the doubly "Dark" Continent. Yesterday, in the Chamber of Deputies, on the part of the Government, Signor Bonin gave official details of the destruction of Captain Bóttego and his expeditionary force. The importance of the expedition from a geographical and commercial point of view was immense. The "objective" was Lug on the Juba River, there to found a station in Italian Somalia, at which the rich products of the Borana and Galla countries might be made to converge for transmission to the Benadir; to explore the basins of the Gava and of the Omo, resolving the problem of the downward flow of the Juba, and to examine the regions between the Nile and Lake Rodolfo. Captain Bóttego left Brava in the Benadir on Oct. 12th, 1895; reached Lug on Nov. 18th, founded the station, started on Dec. 27th with 180 men along the Ganane and the Gava, and kept the Geographical Society informed of his successes till April 22nd, 1896, when it forwarded him news of the disasters in Abyssinia. The bearer of this reached Lug in May and started in quest of the expedition. Meanwhile indirect news of Captain Bóttego and his column as late as October last represented him as having gained the south shore of Lake Rodolfo on his return journey, and further tidings reached London that he was making for the coast of the Indian Ocean, till on April 23rd King Menelik received a despatch announcing that on the Ethiopian frontier towards Baro Captain Bóttego had come into conflict with a native tribe and had been killed, that two other Italians were made prisoners, and that the fourth Italian member of the expedition had not been heard of. Whether this is the medical officer Professor Maurizio Sacchi, whose high accomplishments in nature-study were expected to find a precious field in the explorations, is not yet known; he may possibly be one of the two prisoners. And this is all that is yet ascertained to relieve the agony of suspense in which Italy is condemned to remain, for who knows how long a period. Signor Bonin's narrative, of which I give the merest sketch, was heard with breathless interest by the Chamber, which passed a resolution expressing heartfelt condolence with the octogenarian father of the bright and brave Captain Bóttego.

(FROM OUR OWN CORRESPONDENT.)

Infectious Diseases Hospital for Melbourne.

THE necessity of establishing in Melbourne a hospital for the isolation and treatment of infectious diseases has long been felt to be urgent, and it has been now decided to erect such an institution as a memorial of Her Majesty's Diamond Jubilee. A large public meeting was held in the Melbourne Town Hall on March 27th, His Excellency the Governor presiding, at which it was resolved that the best means of commemorating the long and glorious reign of Queen Victoria was by the establishment of an Infectious Fever Hospital. It is proposed to raise about £20,000 for the building and equipment of the institution, the maintenance of which will devolve upon the municipalities in accordance with the Health Act. A very large and influential central committee has been formed to collect the necessary funds, and local committees are to be formed throughout the colony. A large sum has already been given, including a donation of £1000 from the proprietors of the *Melbourne Argus*, and the Government has promised to give a suitable piece of ground as a site for the building.

The Quarantine Arrangements for Melbourne.

The Board of Health of Victoria has forwarded to the Minister of Health a lengthy report on the quarantine arrangements. The Board states that the sanatorium for small-pox patients is in a most unsatisfactory condition. The land is undrained, and there is no proper method for disposing of waste and fouled water. The huts which serve as wards are cold, draughty, improperly ventilated—the in-door air being contaminated by soil emanations—and most inadequately lighted. There are no proper arrangements for cooking, bathing, or disinfecting, and the wood and felt construction of the buildings make it impossible to thoroughly disinfect the wards. No appliances have been provided for extinguishing fire, and the want of a well-drained exercise-ground has a depressing effect upon convalescents. Finally, the accommodation is wholly inadequate. The board also urges that the salary of each of the two port health officers at Williamstown should be raised to £300 per annum, and that the salary of the health officer at "The Heads" should be £600 per annum, and that he should not be allowed to engage in private practice, but might occasionally exchange positions with the medical inspector of the board. The Government has decided to give only £500 a year for the last position, and is considering the other matters in the report.

Sanitary Conditions of State Schools and Railway Stations in Victoria.

At the last meeting of the newly-formed Society of Medical Officers of Health of Victoria a report was submitted on the Sanitary Condition of the State Schools and Railway Stations in Country Districts. The supply of drinking water especially was bad. Hardly any of the schools were provided with filters; in many cases the supply was from underground tanks adjacent to urinals, and the same occurred at railway stations. At one station "the water-supply is obtained from the river, and the drainage from the urinal at the station enters the river within a couple of yards above where the water is pumped for the station supply," which is not filtered. The local health officer had reported the matter to the local board of health without avail. The report also stated that as a rule the schools were imperfectly ventilated, and in many instances had not proper drainage. The walls of many of the class-rooms wanted cleaning, having gone without lime-washing for four or five years. Cases of ringworm and ophthalmia were frequent among the scholars, and it could readily be understood how they were transmitted under such conditions, especially in a school where, with an average daily attendance of 800 pupils, a single towel was in use.

Proposed Sanatoria for Consumptives in Queensland.

In reply to a deputation from the Queensland Medical Society asking that sanatoria for consumptives should be established in several suitable country districts, the Home Secretary said he would do what he could in the matter and that he sympathised with the views of the deputation. Arrangements have been made for the establishment of a ward for consumption at the hospital at Roma and also at Dalby. In a paper on the Climatic Treatment of Consumption in Queensland Dr. D. Hardie points out that Dalby, Roma, and Charleville, in South-western Queensland, are admirably suited for the treatment of phthisis during the hot months from October to April, as also a high altitude station, Stanthorpe on the Dividing Range, and that Mount Tambourine, in South-eastern Queensland, is *par excellence* the station best suited for early cases during the cooler months from May to September.

Cold Bath Treatment of Typhoid Fever.

Dr. F. E. Hare has published the statistics of ten years' experience of Brand's system of the cold-bath treatment of typhoid fever at the Brisbane Hospital. The results for five years previously to the introduction of the system gave a mortality of 14·8 per cent.; for the ten years under review a mortality of 7·5 per cent. The reduction was in cases dying from other causes than perforation and hæmorrhage, the percentage mortality from these two causes remaining practically unaltered, and the same as that given by Murchison. The series of 1902 cases included every case admitted, and consequently many cases that were not bathed at all, either because it was contra-indicated, or because they were moribund on admission, or because the pyrexia was not sufficiently high; it was therefore essentially a hospital typhoid death-rate.

Obituary.

WALTER RIVINGTON, M.B., M.S. LOND., F.R.C.S. ENG.,

FELLOW OF THE UNIVERSITY OF LONDON, MEMBER OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND CONSULTING SURGEON TO THE LONDON HOSPITAL.

BY the death of Mr. Walter Rivington, which occurred on Saturday evening last at his country house at Epping, the medical world has lost a prominent figure, and all the causes which can be generically implied by the term "medical reform" an ardent advocate.

Walter Rivington was born in December, 1835, at Highgate, and had consequently reached the age of sixty-one at his death. His father, Mr. George Rivington, was a member of the well-known publishing firm of Rivington and Co. He was educated at Sheffield Collegiate School under the late Dr. G. A. Jacob, afterwards head-master of Christ's Hospital, and proceeded thence to London University, where he had a distinguished career, being an indefatigable prize-winner. He graduated in 1858 in Arts, and five years later proceeded to the degree of Bachelor of Medicine, which he took with honours, being awarded the Gold Medal. In the following year—that is, in 1864—he took the degree of Master of Surgery, again obtaining the gold medal of the University. In the meantime he was walking the wards of the London Hospital, his choice of a medical school being determined by the fact that his cousin, T. B. Curling, was surgeon to the great Whitechapel hospital. At the same time, in accordance with the very commonly followed custom of the day, he was serving his indentures with a general practitioner at Stepney. While a student at the London Hospital he shared rooms with the late Sir Morell Mackenzie, for whom he always entertained a sincere regard, and both young men were frequent speakers at the London Hospital Debating Society. At the hospital Walter Rivington showed exceptional brilliancy as a student, and upon becoming qualified as M.R.C.S. in 1859, he was appointed house surgeon. In 1863, having taken the Fellowship of the College, after a brief service with the Peninsular and Oriental Steam Navigation Company, he was elected to fill the posts of assistant surgeon and demonstrator of anatomy, succeeding to the vacancy caused by the promotion of Mr. Jonathan Hutchinson to the full staff. During the tenure of these posts he displayed great energy, and his services as a teacher in the latter capacity were so much appreciated by the students that they presented him with a testimonial. In 1865 he was appointed lecturer on anatomy in succession to John Adams, a post he held until 1884, when he resigned upon taking up the lectureship on surgery. He could have received this appointment earlier, but preferred the lectureship in anatomy.

In 1870 he was appointed full surgeon, and held the post for the regulation period of twenty years, when he was made consulting surgeon; and with his retirement from the active staff his lectureship in surgery came to an end in 1890. At one time he devoted himself to the study of aural surgery

Hosted by Google

and was the first aural surgeon with a special department; but after a time he discontinued the practice of aural surgery as a special study. He succeeded John Adams as secretary to the London Hospital Club, a body of which he was the moving spirit up to the time of his death, having held the secretaryship for some thirty years. He was thus a bond between various generations of students, keeping alive the hospital traditions; and his eminent services to the club and the hospital were, a few years ago, recognised by a dinner given in his honour, at which a present was made to him of a handsome service of plate. For several years, also, he was dean of the medical school, and made great efforts to promote its success by the institution of entrance scholarships. As a lecturer he was able, impressive, and humorous, and exceedingly popular with the students. He was gifted with an extraordinary memory, and upon several occasions—notably that of his introductory address at the opening of the Medical College and his oration at the Hunterian Society—he committed his addresses to memory, after carefully writing them out, and delivered the whole from beginning to end without hesitation. The former oration will be remembered by some of the older students of the hospital as one of the most strong and eloquent addresses to which they ever listened.

As an operating surgeon it must be allowed that Mr. Rivington made no decided mark, though he could be on occasions very brilliant; and a certain absent-mindedness, which was very characteristic, made him an unequal teacher at the bedside. His enormous experience made him, when his interest was aroused, most instructive, but there were times when he did not seem called upon to exert his undoubtedly high gifts of exposition and lucid description. His professional writings, which were fairly numerous, were characterised by extreme care and thoroughness; and his essays on "Rupture of the Urinary Bladder" and "Tumours of the Orbit," which were reprinted, formed exhaustive digests of their subjects at the time of their publication. His most important, in one sense, and voluminous writings were the two Carmichael Prize essays of the Royal College of Surgeons in Ireland, the one published in 1879 and the other in 1887. The subject of both was the same—namely, "The Medical Profession," and they dealt with the history of the profession from the earliest times until the date of publication. They form perhaps the only complete account of the history, development, character, and laws relating to the medical profession in existence, and the essay bearing the date 1887 is characterised by the most extreme historical and verbal accuracy.

From 1879 to 1883 Mr. Rivington was an examiner to the Royal College of Surgeons of England, and in 1891 he was elected to the Council of the College, standing as the candidate of the reform party. On the Council he was faithful to his pledges, his voice and vote being immediately exercised in behalf of obtaining for the Members of the College a share in the management of their own collegiate affairs. Last year it will be remembered that Mr. Rivington came forward as a candidate for a seat upon the General Medical Council as a direct representative of the profession, and he used his known views on the subject of corporate representation on the Council of the Royal College of Surgeons of England as an admirable argument why he should be supported by one very large class of the profession in England. He considered that the representative of the Royal College of Surgeons of England upon the General Medical Council was no true representative of the College because he was selected by a Council not itself chosen by the corporation but only by a select class of the corporation, and his election literature addressed to the Members of the College seeking their suffrages was excellently clear and outspoken. Had Mr. Rivington been earlier in the field he would perhaps have obtained a seat.

Mr. Rivington's love of justice and his pertinacity against opposition were never better shown than in his ardent espousal of the cause of Mr. R. B. Anderson, as put forward by the Civil Rights Defence Committee. Appointed by the Royal College of Surgeons of England as one of their representatives on that body Mr. Rivington never ceased to urge upon the College the necessity of granting something more than academic support to a movement which used as the main justification for its existence the necessity of defending the professional well-being of one of the Fellows of the College.

Mr. Rivington was for the past three or four years a member of the Annual Committee of Convocation of the University of London, and was a consistent opponent of the scheme for altering its constitution as recommended by the Cowper Commission. He held that by this scheme the real governing body would be a small Academic Council; that the powers of Convocation would be altogether taken away; that there was danger that the standard of examinations would be lowered and that the Imperial character of the University would be forfeited. In June, 1896, he was nominated for the Fellowship of the University in opposition to Sir Joseph Lister, who strongly supported the scheme for the re-constitution of the University into a teaching body. Mr. Rivington was elected by 963 votes against 846.

From the foregoing short memoir it will be seen that Mr. Rivington was a man of marked and generous character. An exceedingly determined man he ran the risk of appearing over-pertinacious and even obstinate; but his efforts were always directed towards effecting what he believed to be reforms and were singularly free from all taint of selfishness. He was deeply aware of the necessity for the amelioration of many of the conditions now existent in the professional life of his poorer brethren, and he spared himself no trouble to make his beliefs shared by others.

HENRY VANDYKE CARTER, M.D. LOND., M.R.C.S. ENG.

DR. HENRY VANDYKE CARTER, Deputy Surgeon-General, I.M.S., and honorary surgeon to the Queen, died at his residence at Scarborough on May 4th. Born on May 22nd, 1831, he was the son of the late Mr. Henry Barlow Carter and brother of the late Mr. Joseph Newington Carter, both well-known artists. He received his early education at the Hull Grammar School under his uncle, the late Mr. John Dawson Sollitt, the friend of Lindley Murray, the grammarian, and himself a man of considerable literary and scientific attainments. While at this school Dr. Carter is said to have received that bent in science in which he afterwards became so distinguished. After leaving the grammar school Mr. Carter studied for some time at St. George's Hospital, London, and became a Member of the Royal College of Surgeons of England and Licentiate of the Society of Apothecaries of London. in 1852 Four years afterwards he graduated M.D. at the University of London. On Jan. 27th, 1858, he was appointed Assistant Surgeon in Her Majesty's Indian Medical Service.

In India he was appointed professor of anatomy and physiology at the Grant Medical College, and it was here that the principal part of his life's work was done. The part which he played in the scheme, approved by Lord Reay, of appointing honorary physicians and surgeons to the Sir Jamsetjee Jeejeebhoy Hospital was an important one, and Lord Reay found in him a warm supporter of medical reform. His interest in the spread of medical education in India is shown by the fact that on his retirement he made a donation of 10,000 rupees to the Grant Medical College to found a lectureship in physiology to be named after Lord Reay. During the Indian famine of 1876–80 large numbers of starving people came to Bombay in search of food and work, and a disease which at that time appeared to be quite new to the medical profession of this country broke out among them, and was recognised by Dr. Carter as relapsing fever. After repeated investigations he published "Spirillum Fever—Synonyms, Famine or Relapsing Fever, as seen in Western India," with plates (London, 1882, 8vo.), for which work he gained the Stewart Pathological Prize of £500 awarded by the British Medical Association. Among his other published works may be mentioned "On Microscopic Structure, &c., of Calculi," "Mycetoma; or, the Fungus Disease of India," and "Leprosy and Elephantiasis." The value of his researches in leprosy was recognised by the British Government and he was officially sent to Norway to inquire into the cause of leprosy in that country.

Dr. Carter inherited some of the talent of his father and was an artist as well as a medical man. The merits of his work as an illustrator of Gray's Anatomy will be known to most medical men.

Medical News.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—The following candidates have passed the fourth professional examination in the subjects indicated:—

Completed the Examination.—H. E. V. Blake, J. J. F. Bourke, J. G. Cookman, H. E. Eardley, J. R. Hewetson, J. O'M. Irwin, W. J.

Hosted by Google

Keane, G. G. H. Moorhead, J. D. Murdoch, Thos. J. Potter, C. J. Powell, A. W. Sampey, and V. B. Taylor.
Medicine.—W. M. Jones, J.M. Longford and B. R. Phillipson.
Surgery.—J. M. Longford.
Midwifery.—W. C. W. Glenny.
Ophthalmology.—D. F. Clarke, W. M. Jones, C. J. D. Odevaine and B. R. Phillipson.
Hygiene, &c.—L. E. Fannin.

The following candidate has passed the examination for the Diploma in State Medicine :—

Thomas Carr, M.D. Durh., M.R.C.S. Eng., &c.

UNIVERSITY OF CAMBRIDGE.—At the third examination for the degrees of M.B. and B.C., Part II. (Medicine, &c.), the following were examined and approved (all the candidates being Bachelors of Arts) :—

Barraclough, Christ's; Bumsted, St. John's; Cayley, Trinity; Cooper, Emmanuel; Delbruck, King's; Dove, Christ's; Heywood, Emmanuel; Houseman, Clare; Hughes, Caius; Hutchinson, Trinity; McDougall, St. John's; Mackenzie, Caius; Muir, Emmanuel; Myers, Caius; Pendlebury, Pembroke; Porter, Emmanuel; Robinson, Caius; Stead, Caius; Turner, Emmanuel; Twigg, Christ's; Ward, Selwyn; and Watson, Peterhouse.

On May 7th twenty-five new students were admitted to the University, making the total entry for the year 949. Examinations for science scholarships and exhibitions for candidates not yet in residence will this year be held by St. John's, Trinity, Pembroke, Gonville and Caius, King's, Jesus, Christ's, and Emmanuel Colleges on Nov. 2nd. The examinations at St. Peter's and Sidney Colleges will begin on Nov. 30th, and at Clare and Trinity Hall on Dec. 7th. Details may be learned on application to the tutors of these Colleges. The deputy Professor of Pathology, Dr. A. A. Kanthack, M.A., of St. John's College, has been appointed Pathologist to Addenbrooke's Hospital. The agitation with regard to women's degrees is being conducted with increasing zeal. The Vice-Chancellor has received a memorial signed by 2100 resident "persons *in statu pupillari*," protesting against the grant, and a counter memorial signed by 298 in its favour. A notice of *non placet* in the name of some 280 resident masters and doctors has been issued; the list appears to include most of the medical teachers, and about 110 tutors and lecturers. Entirely new arrangements for the recording of the votes, which are expected to number 3000, are being made at the Senate House, where the decision will be taken on May 21st between 1 and 3 P.M.

ROYAL COLLEGE OF SURGEONS IN IRELAND. At a meeting of the President, Vice-President, and Council, held on May 4th, the following examiners were elected for one year:—Anatomy: John Barton, F.R.C.S., and Alexander Fraser, F.R.C.S. Surgery: Arthur Chance, F.R.C.S., and R. Glasgow Patteson, F.R.C.S. Physiology and Histology: J. Alfred Scott, F.R.C.S., and Charles Coppinger, F.R.C.S. Biology: J. Alfred Scott, F.R.C.S., and George Burbridge White, F.R.C.S. Pathology: Edward H. Taylor, F.R.C.S., and John J. Burgess, F.R.C.S. Midwifery and Gynæcology: Richard T. Hearn, F.R.C.S. Ophthalmology: Patrick Wm. Maxwell, F.R.C.S., and John Benjamin Story, F.R.C.S. Sanitary Law and Vital Statistics: D. Edgar Flinn, F.R.C.S. Bacteriology: J. Alfred Scott, F.R.C.S. Engineering and Architecture: J. Charles Wilmot, C.E. Dental Surgery and Pathology: Arthur W. W. Baker, F.R.C.S., and R. Theodore Stack, F.R.C.S. Mechanical Dentistry: Shenstone J. Bishop, L.D.S. R.C.S., and George W. Yeates, L.D.S. R.C.S. Chemistry and Physics: J. Dallas Pratt, F.R.C.S., and Edwin Lapper, F.R.C.P. Languages: L. J. Woodroffe, M.A. Mathematics, Physics, Dictation, and English Essay: J. W. Tristram M.A.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Krocker, the chief medical officer of the garrison, and Dr. D. Hansemann, *privat-docent* of Gynæcology, have been granted the title of Professor.—Dr. Paul Strassmann has qualified as *privat-docent* in Gynæcology.—*Bonn:* Dr. Kruse, *privat-docent*, has been granted the title of Professor.—*Budapest:* Dr. Alexander Korányi, *privat-docent* of internal medicine, has been appointed Extraordinary Professor.—*Cracow:* Dr. Julian Nowak, of Vienna, has qualified as a *privat-docent* of Pathological Anatomy.—*Halle:* Dr. Sobernheim has qualified as *privat-docent* of Hygiene.—*Geneva:* Dr. J. L. Prevost, Professor of Therapeutics, has been appointed Professor of Physiology, in succession to the late Dr. Schiff.—*Kazan:* Prince Argutinski-Dolgoruki, Extraordinary Professor of Pediatrics, has been promoted to the rank of Ordinary Professor.—*Lemberg:* Dr. Louis Rydygier, of Cracow, has been appointed Professor of Clinical Surgery.—*Philadelphia Polyclinic:* Dr. Addinell Hewson and Dr. Joseph S. Gibb have been appointed Professors of Anatomy and Laryngology respectively.—*Strasburg:* Dr. Ernst Levy, *privat-docent* of Internal Medicine and Bacteriology, has been promoted to an Extraordinary Professorship of those subjects.

BIRKENHEAD MEDICAL SOCIETY.—At a meeting on May 7th, the President, Dr. R. Sydney Marsden, being in the chair, the following cases were shown:—Dr. Blood: (1) Cases of Squint; (2) Cataract Extractions; (3) Congenital Absence of Iris in Mother and Child. Mr. Shears: (1) Two Cases of Interstitial Keratitis; (2) Case of Hereditary Optic Atrophy; (3) Case of Specific Choroido-retinitis; (4) Extreme Hyperæmia of Both Discs due to hypermetropic astigmatism and closely simulating optic neuritis of disease. Mr. Stansfield: (1) Ligature of Internal Saphenous Vein for intractable Varicose Ulcer; (2) Skiagraph of Cranium; (3) Case of Umbilical Hernia. Dr. Carden Pearson: (1) Varicose Veins of Thorax; (2) Successful Case of Ligature of Innominate Artery for Subclavian Aneurysm. Mr. Stewart: (1) Rodent Ulcer of Eyelid; (2) Ulceration of Tonsil; (3) Chronic Hydrocephalus in a boy aged eleven years. Mr. Laird Pearson: Plastic Operation for Repair of Hare-lip in a grown-up child.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Owens College, Manchester, on April 23rd, Mr. H. Briggs, President, being in the chair.—Dr. T. B. Grimsdale (Liverpool) narrated a case of Atresia Vaginæ together with Double Hæmatometra and Double Hæmatocolpos. The patient was sixteen years of age. She complained of pain in the lower abdomen and sacral region and had never menstruated. She had passed "yellow jelly" from the bowel. She was well nourished and well developed. The external genitals were well formed. An opening which had the appearance of the vaginal orifice admitted one finger into the bladder. This was really a cul-de-sac about half an inch deep, into which the urethra opened. An operation was performed and the condition relieved by a central perineal incision. The condition found at the operation was atresia of the lower portion of the vagina—about two-thirds; above this the vagina was double and each vagina led into a separate uterus, all these cavities being distended with blood. At a subsequent date the condition was verified to be uterus didelphys and vagina duplex.—Dr. Gemmell (Liverpool) related a case of Puerperal Septicæmia from an unusual cause. On the ninth day after delivery the patient's temperature went up to 104° F. The interior of the uterus was quite clean and smooth, but there was an abscess cavity in the pouch of Douglas from which sloughs came away. There was no pelvic cellulitis.

BRITISH ORTHOPÆDIC SOCIETY.—A meeting of this society wes held on March 12th at the West London Hospital, Mr. C. B. Keetley being in the chair.—Mr. Jackson Clarke showed a case of Spontaneous Inward Displacement of the Scaphoid Bone unaccompanied by Flat-foot, but attended with a good deal of pain. There was also a distinct depression externally to the scaphoid bone.—Mr. Tubby described a similar case in which he had, after failure of other means, chiselled off the prominence of the scaphoid.—Mr. Muirhead Little thought that the condition was similar to that described by Schäffer under the title of "non-deforming flat-foot."—Mr. Noble Smith drew attention to the accounts of the immediate reduction of the deformity arising from Pott's disease as practised by Dr. Calot, and he questioned if it were possible that such a procedure had been followed by the results described. As showing the possibility of a very large gap in the spinal column becoming filled by bone, he alluded to a specimen of his own which had been filled up with soft new bone.—Mr. Robert Jones mentioned certain cases in which attempts at forcible straightening had been followed by disastrous results.—Mr. Luke Freer described a simple instrument for cases of Hallux Valgus.—Mr. Keetley showed a girl, aged thirteen years, on whom he had operated for Congenital Dislocation of the Hip three months previously. After extension and division of the contracted muscles he had opened the capsule of the joint and gouged out a new acetabulum. There was now shortening of an inch and a quarter, with a good deal of flexion movement, but no upward displacement of the femur could be obtained.

NOTES ON CURRENT TOPICS.

The Duty on Tea.

IN the House of Commons on Monday, May 10th, a proposal was made to reduce the duty on tea from 4*d.* to 2*d.* per lb., but the Chancellor of the Exchequer and the Government opposed it, and it was rejected by a very large majority. In the course of his speech the Chancellor of the Exchequer called attention to the fall in the price of tea in recent years, and with regard to the quantity consumed by the population of the United Kingdom he said it had increased from 4·51 lb. per head in 1875-76 to 5·24 lb. per head last year.

HOUSE OF COMMONS.

THURSDAY, MAY 6TH.

London Hospital Medical School.

Mr. MacNeill asked the Secretary of State for the Home Department whether the London Hospital Medical School was registered under 39 and 40 Vic., cap. 77, in the years 1895 and 1896 for the performance of experiments on living animals; whether the Government inspector in his report, dated July 5th, 1896, stated "that the names of all those 'licensed places' to which licensees were accredited were given in the tables"; and whether, having regard to the fact that the London Hospital had been omitted from the tables of the Government inspector's report for the year 1895, the Home Secretary would order an amended report of the experiments on living animals to be issued which should be accurate.—Sir Matthew White Ridley said that the answer to the first two paragraphs of the question was in the affirmative. There had been no inaccuracy, however, in the return. The hon. member would find the London Hospital mentioned in the footnotes to Table I. on pages 13 and 15. He must certainly decline to issue an amended table, but to meet what he imagined were the hon. member's wishes he had directed that in future returns all registered premises should appear in the body of the table, whether or not any experiments were performed in them.

Marching Powers of the Guards.

Mr. Arnold Forster asked the Under Secretary of State for War whether it was a fact that after six days' route marching undertaken by battalions in the Brigade of Guards 220 men of the 2nd Grenadiers were reported sick and 12 men of the 2nd Coldstream Guards; what was the total marching-out strength of the battalions referred to; and how many of the men in each were respectively long-service men, short-service men, or men enlisted for three years.—Mr. Brodrick replied that the facts were not as stated. The 220 men of the Grenadiers were the total number who during the six days in question were for any cause seen by the medical officer. No record of such men was kept by the Coldstream Guards. The number who fell out was 22 in the Grenadiers and 6 in the Coldstreams, and the admissions to hospital were severally 17 and 6. The marching-out strength was 1460 Grenadiers and 980 Coldstreams. The three-year men numbered 576, the seven-year men 789, and there were 145 men of more than seven years' service, but these only referred to the 1st and 2nd Battalions of the Grenadier Guards and to the 2nd Battalion of the Coldstream Guards. The similar returns of the 3rd Grenadiers and 1st Coldstreams had not been received.

Pulmonary Complaints in the Navy.

Captain Phillpotts asked the First Lord of the Admiralty whether, out of a batch of 80 men surveyed at Haslar Hospital and found unfit for further service in Her Majesty's navy, the majority were young stokers with less than six months' service who were incapacitated by pulmonary complaints; and if the Government had any plan to check the development of such diseases among this class.—Mr. Goschen said he had seen a statement to the effect of the hon. and gallant member's question, but it was entirely incorrect, and he regretted its publication as tending to create apprehensions for which there was no foundation. The statement suggested that out of 80 men surveyed the majority were young stokers with less than six months' service incapacitated by pulmonary complaints. As a matter of fact, out of 76 men and boys who were invalided at Haslar last month on the occasion in question only 18 were stokers, and of these both young and old only 8 were found unfit on account of pulmonary disease. Of these 8, 5 were twenty-two years of age and upwards.

Nursing in Scottish Prisons.

Mr. Hedderwick asked the Lord Advocate whether, under the present Scots prison system, prisoners on the sick list were dependent for nursing solely upon the offices of any two fellow criminals (without test of knowledge or capacity) who might happen to be placed in the same cell; and if so, whether, having regard to the fact that this system had been condemned and abolished both in England and Ireland, he would take steps to secure its abolition in Scotland also, and the substitution in lieu thereof of adequate provision for the proper nursing of sick prisoners by trained infirmary warders or otherwise.—The Lord Advocate replied that the hon. member had been misinformed. Special "nurse" warders were appointed where necessary. In other cases nursing duties were performed either by the ordinary warder staff or by specially selected prisoners. When prisoners were very ill there was power to send them to a hospital with the assent of the sheriff. The existing system worked satisfactorily, and he saw no reason for altering it.

Precautions against Fire.

Mr. Aird asked the Secretary of State for the Home Department if, having regard to the terrible calamity in Paris, he would be willing to appoint a committee or a commission to consider the desirability of some further measures being taken for the safety of the public in this country, not only for theatres but for public meetings and bazaars.—Sir Matthew White Ridley replied that he believed this important question had already been considered by more than one committee, including the Select Committee of 1892, and he could not say that at present it seemed to him to be necessary to have a fresh inquiry. He would carefully consider, however, the question of whether any, or what, legislation could be introduced further on with the view of securing the public so far as might be possible against the occurrence of any such terrible disaster as had happened in Paris.—Mr. Aird asked whether the Home Secretary was aware that at the present time there was no control whatsoever as regards inspection of bazaars against fires.—Sir Matthew White Ridley said he was quite aware that there was no control except over places which happen to be licensed for other purposes, when it was possible to attach to the licence a condition which ensured some security for life against fire. But it was a very difficult question upon which to legislate, and he could not see at present that as far as regards the information he had, which had been supplied by the various committees of inquiry, there was any necessity for further investigation. That there ought to be some legislation he thought was very possible, and to that he was prepared to give his most earnest attention.

TUESDAY, MAY 11TH.

Sanitation at Aldershot.

Sir Walter Foster asked the Under Secretary of State for War, whether he was aware that the Aldershot Camp Sewage Farm, although much improved in its general condition, was still unsatisfactory as regards the character of the effluent; and, whether it was the intention of the authorities to expend the extra money necessary to render the present farm successful; or whether it was intended to remove the operations to another site at a greater distance from the camp.—Mr. Brodrick said that this subject, which was a very difficult one, and had been discussed with reference to the treatment of the sewage of the town as well as of the camp, was still under consideration, and there were some points which were not yet cleared up, but the Secretary of State hoped to arrive at a decision very shortly.

WEDNESDAY, MAY 12TH.

Sunday Closing in Ireland.

At this sitting the House gave a second reading to a Bill to extend Sunday closing of public-houses to the five exempted towns in Ireland of Dublin, Belfast, Cork, Waterford, and Limerick, and to increase the *bonâ fide* qualification from three to six miles.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ALLPORT, WILFRID, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Queen's Hospital, Birmingham.

ASHE, C. S., M.B., B.S. Vict., has been appointed Junior Resident Assistant Medical Officer for the Crumpsall Workhouse, Manchester Township.

BADOCK A., M.B, B.S. Durh., has been appointed a Resident Medical Officer for the Williams District, Western Australia.

BEESTON, JAS. L, L.K.Q.C.P. Irel., M.R.C.S., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

BREMNER, D. C., M.B., C.M. Edin., has been appointed Medical Officer for the Workhouse and the Bishop's Castle No. 1 Sanitary District of the Clun Union.

CLARKE, WM., M.R.C.S. Eng., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

COWIE, R. M., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to King's College Hospital.

DAVIES, H. A. B., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed a Public Vaccinator for South Australia.

DENNIS, G. E., M.B., Ch.B. Melb., has been appointed a Resident Medical Officer for Esperance, Western Australia.

DICK, JAS. A., M.D. Edin., has been re-appointed an Honorary Visiting Medical Officer to the Asylum at Randwick, New South Wales.

DIXSON, T. S., M.B., Ch.M. Edin., has been re-appointed an Honorary Consulting Physician to the Asylum at Randwick, New South Wales.

EAMES, W. L., M.B., Ch.B. Dubl., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

ERHARDT, C. C. J., M.R.C.S., L.R.C.P. Lond., has been appointed House Accoucheur to King's College Hospital.

EVANS, THOS., M.R.C.S. Eng., has been re-appointed an Honorary Consulting Surgeon to the Asylum at Randwick, New South Wales.

FLUX, GEORGE, M.D. Brux., M.R.C.S., L.R.C.P., L.S.A., has been appointed Anæsthetist to the British Lying-in-Hospital, Endell-street, Long-acre, London.

FOX, R. A., M.B., M.S. Edin., has been appointed an Assistant Medical Officer for the Lunatic Asylum at Auckland, New Zealand.

GALLOWAY, A. RUDOLF, M.A., M.B., C.M. Aberd., has been appointed Surgeon to the Aberdeen Ophthalmic Institution, vice Jas. McKenzie Davidson, resigned.

GLADSTONE, HOWARD B., M.B., M.S. Edin., has been appointed House Physician to the Bradford Infirmary, vice C. Carew Webb, resigned.

GREENWOOD, FRANK R., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Physician to the Queen's Hospital, Birmingham.

HARRISON, WM. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer of Health for Gladstone, South Australia.

HASSLACHER, F. J., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to King's College Hospital.

HESTOR, J. W., M.B., Ch.M. Syd., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

HUMPHRY, ERNEST, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Health and Medical Officer for Townsville, Queensland.

IRWIN, WM., M.B., M.S. Glasg., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

JACOB, F. H., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to King's College Hospital.

Hosted by Google

JAMES, M. B., M.B., Ch.B. Vict., has been appointed an Assistant Medical Officer for the Highgate Infirmary, vice S. C. Smith, resigned.

JOYCE, J. F., L.R.C.P., L.R.C.S. Edin., has been appointed Officer of Health for the Shire of Poowong and Jeetho, Victoria, Australia.

KELLOCK, T. H., M.A., F.R.C.S., has been appointed Assistant Surgeon to the Hospital for Sick Children, Great Ormond-street, Bloomsbury.

KELLOCK, T. H., F.R.C.S., has been appointed Assistant Surgeon to the Middlesex Hospital, vice L. Hudson, deceased.

LUDLOW, V. E., L.K.Q.C.P., L.R.C.S. Irel., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

LYNCH, F. S., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Physician to King's College Hospital.

MACDONNELL, L. G., M.B., Ch.B. Dubl., has been appointed a Visiting Surgeon to the Herberton Gaol, Queensland.

MACMAHON, J. ROSS, M.B., C.M. Aberd., has been appointed Clinical Assistant to the St. John's Hospital for Diseases of the Skin.

MARGAREY, S. J., M.D. Melb., has been appointed a Public Vaccinator for South Australia.

MARTIN, JAMES S., M.B., C.M. Edin., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed a Junior House Surgeon to the Sheffield General Infirmary.

MEGGS, THEODORE HUGH EGBERT, M.R.C.S., L.R.C.P., has been appointed Medical Officer to the Eton Union Workhouse and the Upton-cum-Chalvey District, vice W. W. Buée, retired.

MONIER-WILLIAMS, M., M.R.C.S., M.R.C.P. Lond., has been appointed Clinical Assistant to the St. John's Hospital for Diseases of the Skin.

MORTON, JAS. C., M.B. Melb., has been appointed Officer of Health for Broadford Shire, Victoria, Australia.

NICKSON, W. J. R., M.D. Dubl., Ch.B., has been appointed an Honorary Medical Officer to the Newcastle Hospital, New South Wales.

PAGET, STEPHEN, F.R.C.S., has been appointed Surgeon to the Throat and Ear Department of the Middlesex Hospital.

PARDEY, JAS. M'I., M.B., Ch.B. Melb., has been appointed (*pro tem.*) Health Officer for the Port of Launceston, Tasmania.

ROBIN, V. J. R., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Health and Medical Officer for Port Douglas, Queensland.

ROBINSON, THOMAS, M.R.C.S. Eng., L.R.C.P. Lond., D.P.H. Camb., has been appointed Medical Officer of Health for the Borough of Burton-on-Trent.

ROTH, W. E., M.R.C.S. Eng., has been appointed a Visiting Surgeon to the Normanton Prison, Queensland.

RUTHERFORD, JOHN V. W., M.B., C.M. Edin., M.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Infirmary, Newcastle-on-Tyne.

SALTER, G. H., L.R.C.P. Edin., M.R.C.S. Eng., has been appointed Officer of Health for Ballan Shire, Central Riding, Victoria, Australia.

SHUTER, R. E., M.B., Ch.B. Melb., has been appointed Health Officer for Port Augusta, South Australia.

SMITH, A. G., M.D. Aberd., C.M., has been appointed Medical Officer to the boarded-out patients belonging to Dundee Parish in the Newtyle District, Coupar Angus, vice D. M. Mills, resigned.

SMITH, E. TEMPLE, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Obstetric and Ophthalmic House Surgeon to the Queen's Hospital, Birmingham.

SMITH, WILLIAM E., M.B., C.M. Edin., has been appointed Junior House Surgeon to the Royal Eye Hospital, Manchester.

SMITH, G. U., M.B. Lond., has been appointed House Physician to King's College Hospital.

SQUIRE, M. F., M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer for the Paddington Workhouse and Assistant to the Medical Superintendent of the Infirmary.

STAMPER, G. C., M.R.C.S., has been appointed Medical Officer for the No. 4 Sanitary District of the Pembroke Union.

SUTTON, T. S., M.R.C.S., has been appointed Medical Officer for the Norbury Sanitary District of the Clun Union.

THOMAS, JOHN T., L.R.C.P., D.P.H., M.O.H., has been appointed Medical Officer to the Lowestoft School Board.

WARNEFORD LUNATIC ASYLUM, Oxford.—Medical Superintendent and Secretary. Salary £500 a year, with furnished house, coals, gas, garden produce, milk, laundry, and keep for one horse.

WELLINGTON (SALOP) URBAN DISTRICT COUNCIL.—Medical Officer of Health. Salary £50 a year. Applications to the Clerk to the Council, Wellington, Salop.

Births, Marriages, and Deaths.

BIRTHS.

PENNELL.—At Buenos Aires, on May 12th, the wife of G. H. Pennell, M.D., F.R.C.S., of a daughter.

THOMSON—On May 7th, at 243, Queen's-road, New-cross-gate, S.E., the wife of David Thomson, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glasg., of a son.

TIDEY.—On May 10th, 1897, at 10, Via Panzani, Florence, the wife of Stuart Tidey, M.D. Lond., M.R.C.P., of a daughter.

WATERHOUSE.—On May 9th, at Wimpole street, W., the wife of Herbert F. Waterhouse, F.R.C.S., of a daughter.

MARRIAGES.

ADAM—ELMORE.—On May 12th, at St. Stephen's Church, Westminster, by the Rev. W. H. Manning, Dr. John Law Adam, son of John Adam, Esq., of Tullochvenus, Aberdeenshire, to Edith Constance Elmore, daughter of the late Sir Francis Wood, Bart., of Barcombe House, Lewes.

EALES—HUNTER.—On May 5th, at St. Stephen's, Gloucester-road, George Young Eales, L.R.C.P. and L.M. Edin., M.R.C.L. Eng., of 1, Matlock-terrace, Torquay, son of the late Rev. W. T. H. Eales, Vicar of Yealmpton, to Bertha Jane, second daughter of the late Henry Frotheringham Hunter, of Kilbourne Hall, Derby.

FIDO—TREACHER.—On May 13th, at Christ Church, North Brixton, by the Rev. W. R. Mowll, M.A., H. Adamson Fido, M.R.C.S., L.R.C.P. Lond., of Raleigh, Arodene-road, Brixton-hill, S.W., to Ethel May, eldest daughter of George Treacher, Esq., of Wierfield, Loughborough-park, Brixton, S.W.

GARRAD—RIDLEY.—On May 5th, at Reading, Francis William Garrad, M.B., of Starbeck, Harrogate, to Muriel Maud, eldest daughter of Owen Ridley, Esq., J.P., of Orwell House, Reading.

SUMPTER—ROBINSON.—On April 21st, at St. Mary's Church, Hunstaton, Berners George Sumpter, M.B. Durh., M.R.C.S., second son of W. Sumpter, M.D., Oley-next-Sea, Norfolk, to Amy Elizabeth, youngest daughter of C. T. Robinson, Esq., J.P., of Hunstanton, Norfolk.

DEATHS.

BRIGGS.—On May 5th, at Gothic House, Harrow-on-the-Hill, George Chapman Briggs, M.B. Lond., aged 49 years.

CREAM.—On May 6th, at Brighton, Robert Chevallier Cream, M.D., late of Melford House, Putney, aged 83 years.

RIVINGTON.—On May 8th, at Epping, Walter Rivington, M.S., F.R.C.S., of Wimpole-street, W., and Coniston, Epping, aged 61 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

FRIDAY (21st).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-street, W.).—8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (17th).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Abscess of the Liver.

LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. O. Wilkin: Nasal Polypi.

TUESDAY (18th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Buzzard: Lecture.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Seborrhœa.

ROYAL INSTITUTION.—3 P.M. Dr. T. Anderson: Volcanoes (Tyndall Lectures).

WEDNESDAY (19th).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Beri-beri.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.)—5 P.M. Dr. S. Taylor: Surface Anatomy of the Thorax and Abdomen.

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: House Drainage.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Wethered: Cases of Dilated Heart and their Treatment.

SOCIETY OF ARTS.—8 P.M. Dr. P. F. Frankland: London Water-Supply.

THURSDAY (20th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Separation of Proteid Substances occurring in Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Hutchinson: Clinical Lecture.

THE HOSPITAL FOR SICK CHILDREN (Medical School, Gt. Ormond-street, W.C.).—4 P.M. Dr. Barlow: Lecture

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: Surface Anatomy of the Upper Extremity.

FRIDAY (21st).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.)—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. J. Taylor: Electrical Testing and Treatment.

EAST LONDON HOSPITAL FOR CHILDREN.—3 P.M. Dr. J. A. Coutts: On the Treatment of Croupous Pneumonia in Young Children.

LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Anthrax and Malignant Œdema.

ROYAL INSTITUTION.—9 P.M. Rt. Hon. Lord Kelvin: Contact Electricity of Metals.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE SPREAD OF PLAGUE.

THE following is an extract from the memoir of Sir John Drummond Hay, P.C., K.C.B., G.C.M.G., sometime Minister at the Court of Morocco (John Murray, 1896), p. 24:—

"The danger from plague by contagion cannot, however, to my mind be called in question. That dire disease was introduced into Morocco about the year 1826 by an English frigate, which our Government had dispatched to Alexandria, where the plague was then raging, to convey from that port to Tangier two sons of the Sultan, returning from a pilgrimage to Mecca. No case of plague or other illness had occurred on board the frigate during the voyage, and the Sultan's sons and other passengers were allowed to land at Tangier.

"The Custom's officers, being suspicious that in the numerous boxes, brought by pilgrims who had been permitted to embark with the Moorish princes, contraband goods were being smuggled, caused some of the cases to be opened. One contained Egyptain wearing apparel, which the owner said he had bought second-hand, and subsequently confessed had belonged to a person who had died of the plague at Alexandria. The two Moorish officials who opened the boxes were attacked with the plague that night and died in a few hours. The disease spread rapidly throughout Morocco, carrying off eighty per cent. of those who were attacked."

There is probably more truth in the above narrative than in that repeated by Mead (Discourse on the Plague, ninth edition, p. 89), which he says was "communicated to me by a person of undoubted credit," viz.:—

"In the year 1726 an English ship took in Goods at *Grand Cairo*, in the time of the *Plague's* raging there, and carried them to *Alexandria*. Upon opening one of the Bales of Wool in a Field, two *Turks* employed in the *Work* were immediately killed, and some *Birds*, which happened to fly over the place, dropp'd down dead."

GRESHAM LIFE ASSURANCE SOCIETY.

THE forty-eighth ordinary general meeting of the Gresham Life Assurance Society was held on April 27th at the offices, St. Mildred's House, Poultry, E.C. The report showed that the number of policies issued during 1896 was 8654, assuring the amount of £3,223,118. The new premiums amount to £137,768. The result of the operations of the year was to increase the society's funds by £409,961. In seconding the adoption of the report Mr. A. H. Smee, the deputy-chairman and chief medical adviser of the society, said that when visiting their continental branches last year he was very much struck with the great advancement in sanitation and the improvement in the public health that have taken place during the the last quarter of a century. Governments and municipalities have paid great attention to water-supplies and drainage, and since the Franco-German War vaccination and re-vaccination have become compulsory in the German Empire, the result being that small-pox has been practically stamped out, and when a supply of small-pox lymph was required last year for the pathological laboratories of Berlin it was obtained from England. On investigation of 27,000 sets of proposal papers he found that small-pox attacked persons who had not been previously vaccinated in the following ratios: In England, 3 per 10,000 living; France, 27; Belgium, 48; Hungary, 17; Italy, 29; Holland, 86; Austria, 37; Germany, 0; Spain, 81; and Scandinavia, 11. Diphtheria affects life assurance business in an indirect manner, because in certain countries it is a custom for parents to take out endowment assurance policies on their lives to provide dowries for their daughters and education for their sons, and when the child dies there is no longer any object for keeping the policy in force. In the first quarter of the present year London had a mortality from diphtheria of 639 per 1,000,000; Munich, 459; Amsterdam, 373; Berlin, 346; Dresden, 362; Vienna, 324; Copenhagen, 243; Paris, 188; The Hague, 172; Christiania, 150; Stockholm, 118; and Brussels, 43.

X. Y. Z.—There is no rule with regard to purchasing partnerships. When we hear of a practice being sold "at a two or three years' purchase," the gross receipts are implied. Our correspondent's remedy depends upon how far he can show that he has been induced to purchase by incorrect representations. Upon this point his solicitor will advise him, and there is no necessity for the intervention of any society.

"YOUR VERSION OF THE MATTER."

To the Editors of THE LANCET.

SIRS,—I should be glad if you would kindly advise me what course to adopt under the following circumstances. I received yesterday (May 7th) a notice from the secretary of a local club asking me to attend a meeting to be held at an hotel in this town, convened for the purpose of arbitrating on the case of a member who has sued the same club to recover fees paid by him to an outside medical man after I—as the club medical officer—had refused to attend him.

At the time of my throwing up the case I wrote to the secretary of this patient's club, giving a circumstantial account of my professional conduct of the case, together with medical details of the patient's condition and my reasons for refusing to attend him any longer. This letter the club committee still possess, and containing, as it does, all information cognate to the matter, it should serve every purpose as official evidence. But instead of so viewing it I am requested by the secretary to attend a club meeting on the 18th inst. at a public-house to "give your version of the matter" in the presence of the aggrieved member; or, in other words, to be cross-examined by laymen on a point of medical ethics. I have thought it best before replying to obtain the aid of your valuable advice.—I remain, yours faithfully,

May 8th, 1897. FABRICIUS.

*** It is clear to us that our correspondent will do perfectly right not to attend the club meeting in the public-house. He has explained his position to the secretary of the club, and the club must now deal with their member.—ED. L.

C. M. M.—Presumably the change of address has been sent to our correspondent by error. It is not usual for consultant practitioners to notify a change of address to other than their acquaintances, either in business or private capacity.

THE DANGER OF CELLULOID WEARING APPAREL.

A SINGULAR demonstration of the danger of celluloid collars and cuffs under certain conditions comes from Farnham, Surrey. A boy, aged ten years, wore celluloid collars and one day lost his shirt-button whereupon he tied the ends together with string. At bedtime he could not untie the knot, and taking a light placed it against the string to burn it. The collar lighted up immediately and flared all around the poor boy's neck, burning his face and head, while the composition began to run and fall in lighted drops on to his clothing. The throat, we are informed, was badly injured.

A DANGEROUS PERFORMANCE.

DURING the past week a "Professor Morritt" has been exhibiting a hypnotised man at a hall in Cardiff. On May 8th a local publican essayed to win a bet of £50 by awakening the subject. This he proposed to effect by suddenly precipitating the sleeping man into a tank of water six feet deep. After being immersed three times in the presence of a large number of people he showed no signs of vitality, although the "Professor" soon awakened him by a "few magnetic passes." When these playful experiments with the vital centres have ended in some terrible fatality, we suppose public indignation will be aroused against them. Until then, these degrading and dangerous shows will enjoy popularity in spite of all revelations of chicanery and collusion.

M.D.—It is not easy to make the kind of practice desired. If a man desires to pick and choose his cases that he may have just so much occupation as will pleasantly fill his day and add to his private income he must refuse to see many patients. The result will be that he will get the reputation of not being quite in earnest, and medical men more determined to take whatever they can get will gain his practice from him. There are exceptions, of course, but this is the rule in our experience. Probably our correspondent would find Los Angeles as pleasant a place as any. The climate is genial, and the scenery is notoriously beautiful. The rate of living is expensive.

"KNIFE FOR SLITTING OPEN THE TONSILS IN CASES OF LACUNAR TONSILLITIS."

To the Editors of THE LANCET.

SIRS,—Should any of your readers wish to put into practice the suggestion made by Dr. Adolph Bronner in THE LANCET of April 17th, it will be necessary to have the knife he recommends made for the purpose. The pattern has been figured in Messrs. Maw, Son, and Thompson's catalogue for many years, together with others selected from a large number of knives and other instruments made by that firm from my designs. Having informed Dr. Bronner of the fact he was good enough to say that he had overlooked it, the chief object of his communication being to recommend the plan of slitting open the tonsils.

I am, Sirs, yours faithfully,

May 10th, 1897. PROSSER JAMES.

Mr. F. J. Richardson.—Our correspondent might consult Letheby's Cantor Lectures, published in a book entitled "On Food: its Varieties, Chemical Composition, Nutritive Value, Comparative Digestibility, Physiological Functions and Uses, Preparation, Culinary Treatment, Preservation, Adulteration, &c." He might also find what he requires in the works of Pereira, Moleschott, Pavy, Vogel, and Voit.

A FATAL BELL-MAN.

WE extract the following from our contemporary, the *Birmingham Owl*:—

> "We are sorry to say it, but it really seems as if the profession of medicine renders those who follow it peculiarly ungrateful. They are educated for the most part in colleges supported by the charity of the benevolent, and obtain their experience in hospitals maintained by the public, but once they are licensed they cry out because a few people attend the hospitals with ailments a chemist might cure if they had the money to pay him, and a few more who could afford to pay the general practitioner prefer to submit themselves to the specialist whose fees would be beyond them if they consulted him in his own lair.
>
> "The question of fees is of course at the root of the complaint. If there were no hospitals the doctors would earn more, and it irks them to see people obtaining for nothing what they are prepared to sell to them at a big price. It is as though journalists should grumble at people reading papers in a free library instead of purchasing them.
>
> "The matter is one, after all, for the public to decide. The doctors could end their share in it to-morrow if they choose by refusing to act in an honorary capacity. Not that there is any likelihood of their doing so; they know the advantages of an advertisement as well as most men, and the few hours a week many of them give to the hospitals are well repaid by the reputation contact with their numerous patients there gains for them."

We, in our turn, are sorry to say it, but this description of the agitation for hospital reform is as untruthful as it is ungrammatical. Medical men are not educated in colleges supported by the charity of the benevolent; they do not obtain their experience in hospitals maintained by the public, but in hospital schools to which they are compelled to pay large fees; they could not "end their share" in the matter "to-morrow if they choose by refusing to act in an honorary capacity" to hospitals, for it is not the honorary staffs of hospitals who are complaining of the excess of patients so much as those medical men who do not hold these distinguished appointments. It seems to us regrettable that a journal should pillory those who follow the profession of medicine as "peculiarly ungrateful" on grounds that are absolutely false.

THE QUEEN'S JUBILEE INSTITUTE FOR NURSES.

AMID the various philanthropic undertakings on behalf of which appeals are just now being made, special interest attaches to the Queen's Jubilee Institute for Nurses. The institute has an income of £2100 a year, derived from the Queen's gift of £70,000 taken from the Women's Jubilee Offering, but the necessary expenses have far exceeded the income, and a sum of £11,000 contributed by friends during the last seven years for the extension of the work has now been expended, so that the institute has no funds at its disposal to enable it to keep pace with the growing demands for the services of its nurses. In 1896 the number of nurses whose training was completed at the expense of the institute amounted to sixty-six, at an outlay of about £3,000. Their work is to nurse the sick poor in their homes, visiting each patient once or oftener every day, according to the necessity of the case. It is found that one Queen's nurse is about sufficient for every 10,000 of the inhabitants in a town. To the local association which employs her the cost of maintenance is from £80 to £90, which includes all expenses—salary, board, lodging, &c. Promises of support and subscriptions should be sent to the honorary secretaries, Mr. Harold Boulton and Mr. Ernest Flower, M.P., Queen's Commemoration Fund, 64, Cannon-street, E.C.

"*Ubrigin.*"—Samples should be sent to our laboratory for examination.

THE PUBLIC HEALTH EXAMINATION AT CAMBRIDGE.

To the Editors of THE LANCET.

SIRS,—I am one (of whom I dare say there are, or have been, many) of those unfortunates who, at a late stage of their career, have been beguiled by the seductiveness of the study to go in for this examination. I put in an appearance a year ago with the result that I scored enough marks in one subject only, viz., bacteriology, when there was no written paper. This year I scored sufficient marks in everything but bacteriology when there was a paper on that subject, and made a lower percentage in the paper than in the practical work. Among other things we had to stain sections for tubercle, and you may imagine it was no easy matter to see the bacilli even if not much decolourised, when I say that the microscope with the oil immersion seemed to work on a pivot in the centre, and it rested on a table covered with zinc which was so dinted in that there were not four square inches of level surface that I could see. The microscope, thus, on the slightest touch skidded along as if greased. I noticed some of the candidates took the precaution to bring their own microscopes and so had the advantage over others who were foolish enough to expect that everything would be done to facilitate the work given us to do. Perhaps the proper authorities will kindly give this matter their attention. I think in fairness I should have been allowed to present myself under the same conditions as last year—viz., without a special paper on bacteriology. As it is, although in the two examinations taken together I have satisfied the examiners in all, I am no nearer being a D.P.H. than I was a year ago.

I am, Sirs, yours truly,

May, 10th, 1897. N. D.

E. J. B.—Our correspondent will find the information he requires in "A Code of Medical Ethics," by Jukes de Styrap (London: H. K. Lewis).

A NEW FORM OF ADJUSTABLE INVALID CARRIAGE.

MR. JOHN CARTER, of New Cavendish-street, Portland-place, has just constructed for H.R.H. Prince George William of Cumberland a special invalid carriage which embodies several novel features and improvements. A couch was required that could be used in-doors and could also be adapted to wheels for out-door exercise, and in no case was it to appear as an ordinary room couch. Mr. Carter combined all these conditions, and succeeded in designing and producing a carriage which after more than a week's use has proved eminently satisfactory in every respect. The couch or carriage has a removeable side to permit the easy lifting on and off of the occupant. It is upholstered with spring stuffing and fine cloth, is fitted with a back capable of being adjusted to any slope, and has moveable arms which turn back out of the way as may be found necessary. For in-door use the couch is placed on an under frame which supports it at a convenient and comfortable height; for out-door exercise it is transferred to an under carriage, on which it is entirely suspended on four Cee springs with leather braces. The under carriage has four wheels provided with pneumatic bicycle tyres, thereby avoiding all jar and vibration, and has a handle in front by which an attendant can draw it. The couch with the occupant is lifted by two attendants from one of these supports to the other by means of moveable sliding poles, which also enable it to be taken through the doorway of a railway carriage. The great advantage of Mr. Carter's invention is that, although much shorter than the ordinary invalid carriage—a feature which is in several respects a great convenience—it can be used either in a recumbent position or as a chair with the back-rest in a raised position, or as an in-door couch. The carriage is handsome in appearance and design; it can be made of any size.

A MEMORIAL TO HENRY VAUGHAN.

HENRY VAUGHAN the "Silurist" was a notable member of our profession whose memory has been shamefully neglected. Few people have ever heard of him, and fewer still have read his poems. He died on April 23rd, 1695, and was buried in the churchyard of Llansantffraid. For years his grave was dilapidated and uncared for, but recently, we learn from the *Westminster Gazette*, it has been cared for and restored. A memorial tablet has also been put up in the church fixed upon the south wall of the nave. One thing more remains to be done—namely, to enclose the grave with a plain iron railing, and for this some £7 are required. If any medical man should desire to send a subscription towards this object the secretary of the memorial fund is Miss Philip Morgan, Buckingham-place, Brecon. Vaughan was a poet of whom any profession might be proud, and although his works will never, we fear, attain to the height of popularity reached by those of the late Mr. Tupper, they are many of them singularly beautiful and well worth the attention of lovers of true poetry.

PROFESSIONAL CONFIDENCE.

A CORRESPONDENT sends us the subjoined letter, asking us whether we think that such a request should be made to a medical man:—

HEARTS OF OAK BENEFIT SOCIETY.

17, Charlotte-street, Fitzroy-square,
London, W., 30th April, 1897.

DEAR SIR,

EXAMINATION OF CANDIDATES.

The Committee of Management has had under consideration the existing mode of dealing with the applications of candidates who had been rejected on examination for admission to the Society, and I have been instructed to request you, in the general interests of the Society, to be good enough in future cases of rejection to send the Form of Application direct to me marked rejected, with the cause of such rejection, so that we may record such cases.

For this purpose I enclose a few stamped directed envelopes, and thanking you in anticipation,

I am, yours faithfully,
THOS. W. GALLOWAY, Secretary.

It seems to us that it would be a breach of professional confidence to communicate to the secretary the medical reasons why an applicant had been rejected. The case of a medical officer to a life assurance office is, of course, not comparable.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

The Photographic Art

AN AID TO MEDICAL AND SURGICAL SCIENCE.

The utility of photography as an aid to medical and surgical science is so obvious that it is a matter of surprise that its use has been hitherto, comparatively speaking, restricted. As a means whereby clinical results and microscopical researches may be permanently recorded, photography is far more accurate than any drawing can hope to be, and in the hands of the careful worker is capable of producing important results. The successful application of the x rays to surgical diagnosis has undoubtedly acted as a great stimulus to the adoption by medical men of the longer known but somewhat neglected art. Again, the camera naturally appeals to the medical man as a means of relaxation and a scientific hobby after his own heart. In any case the introduction of Photographic "Tabloids" has done much to render the manipulation of plates and prints a matter of much greater ease than hitherto. In the past the great drawbacks, especially to the busy physician or surgeon, have been the time and trouble required to prepare the necessary solutions, and their liability to decompose and become uncertain in composition and action when prepared or purchased ready made.

The Photographic "Tabloid" disposes of every previous objection. Each "Tabloid" contains a definite quantity of photographic chemical, so that no weighing is necessary. There is no danger of deterioration as in the case of stock solutions, for the "tabloid" is dissolved only when required, and furnishes a fresh and active solution for immediate use.

A medical officer writing from Lake Tanganyika, British Central Africa, says: "I always use your 'tabloids' in photography; they are most excellent in every way, uniform in strength, cleanly, inexpensive, and everything to commend them. I have tried all sorts of developers, but none equal your 'tabloids.'"

Photographic "tabloids" occupy very little space, an important point when travelling, and have the additional advantage of being free from the tendency shown by fluids to do irretrievable damage to the other contents of the knapsack should accidental leakage or breakage occur.

PHOTOGRAPHIC "TABLOID" LIST.

Developing "Tabloids":—

Eikonogen, Eikonogen with Quinol; Paramidophenol; Pyro-Developer; Pyrogallic Acid, 1, 2, and 4 grs.; Quinol (Hydroquinone); Pyrogallic Acid with Eikonogen; Quinol with Pyrogallic Acid.

Accelerator "Tabloids."

Restrainer "Tabloids":—

Potassium Bromide, 1 gr.; Ammonium Bromide, 1 gr. *In small and large bottles, 5d. and 9d. per bottle.*

Toning "Tabloids":—

Toning Gold Compound, *in tubes at 8d. each.*

BURROUGHS, WELLCOME & CO,
LONDON AND SYDNEY.

Cable and Telegraphic Address—"BURCOME, LONDON."

'Emol=
Keleet'

A natural powder containing a large proportion of native silicates, employed as a diluent for such potent therapeutic agents as Loretin, Iodoform, Dermatol, Boric Acid, etc., and as a drying and dusting powder.

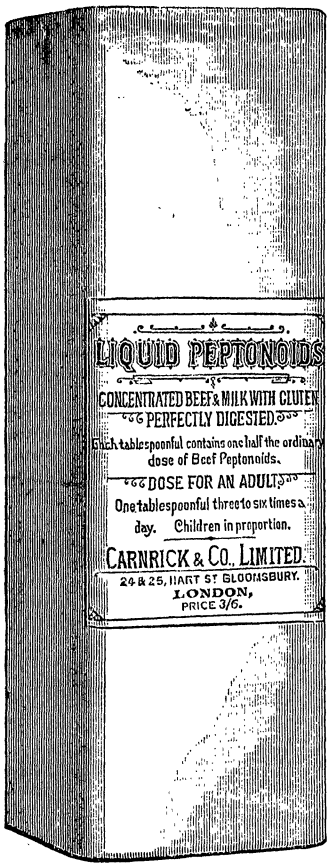
Its soft, silky texture, soothing influence, and other valuable qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other powders have failed.

Supplied in tins at 9d. each.

BURROUGHS, WELLCOME & CO.,
LONDON and SYDNEY.

'Saxin'

(Trade Mark.)



Is a delicious sweetening agent, about 600 times sweeter than sugar, and has been aptly termed 'the sweetest thing on earth.' 'Saxin' is indicated in diabetes, gout, glycosuria, obesity, etc., because it undergoes no change in the system. A 1/4 gr. 'tabloid' of 'Saxin' is equivalent to one lump of best loaf sugar. A small bottle containing 100 or 200 can be easily carried in the vest pocket.

Supplied at 7d. and 1s. 1d. per bottle.

BURROUGHS, WELLCOME & CO.,
LONDON and SYDNEY.

CARNRICK'S LIQUID PEPTONOIDS.

"Liquid Peptonoids" is composed of the essentially nutritive parts of the choicest Beef, and Milk, and Wheat. These constituents have been peptonised and rendered capable of assimilation by the feeblest system, and are dissolved with sufficient alcohol to preserve the preparation, and impart to it the flavour and aroma of a pleasant cordial. It will be found, then, that "Liquid Peptonoids" is a most nutritious food because it is composed of the nutritive elements of our most important foods—Beef, Wheat, and Milk. It is also a food that will be taken and assimilated when other foods are either not tolerated or, not being properly assimilated, do not nourish the system.

"Liquid Peptonoids" has further been found to stimulate the action of the digestive organs. While a food and an aid to digestion, it is also a valuable stimulant and tonic.

"Liquid Peptonoids" has the stimulating property of a pleasantly mild cordial, and so renders useful service in conditions of debility, exhaustion, brain fag, and general and nervous depression. It possesses this great advantage over other stimulants: that, containing nourishing, easily-digested food, the stimulation it affords is not followed by any reaction. *The system is fed at the same time that it is toned and braced up.*

"Readily taken and well borne even by a very delicate stomach."
—BRITISH MEDICAL JOURNAL.

"An invaluable food for invalids whose digestive faculties are impaired. Owing to the predigestive processes, 'Liquid Peptonoids' can be immediately assimilated by the stomach, even in conditions when it cannot exercise for itself the physiological powers of digestion. Bulk for bulk, the Peptonoids contain a proportion of nutritive food which is equalled by hardly any other preparation, but its most valuable feature is that clinically it has proved itself capable of absorption when practically everything else has been rejected by the stomach."—THE HOSPITAL.

CARNRICK'S BEEF PEPTONOIDS
(POWDER).

This well-known food-product consists of the nutritive portion of choice lean Beef, the solids of Milk, and Gluten. It is partially peptonised and thoroughly asepticised. Beef Peptonoids Powder is a Concentrated, Assimilable, and Palatable Nutrient, whose sustaining and recuperative properties have been proved by wide clinical experience extending now over many years.

"It is by far the most nutritious and concentrated food I have ever met with."—PROF. ATTFIELD.

CARNRICK'S SOLUBLE FOOD

Is recognised as the best food that has yet been prepared for infants. It requires no milk, is very Nutritious, Palatable, and Assimilable, and in composition closely imitates Mothers' Milk.

SAMPLES FREE TO MEDICAL MEN.

An Oration

ON

THE MEDICAL SOCIETY OF LONDON IN THE EIGHTEENTH CENTURY.

Delivered before the Society on May 17th, 1897,

BY EDMUND OWEN, M.B.LOND., F.R.C.S.ENG.

SENIOR SURGEON TO ST. MARY'S HOSPITAL, LONDON.

MR. PRESIDENT AND GENTLEMEN,—On Wednesday next, May 19th, the Medical Society of London will be entering upon the 125th year of its existence. The first meeting was held on Wednesday, May 19th, 1773. Our illustrious Lettsom attended it, his name appearing second upon the list of those who had the honour of being present at its birth. At that first meeting the rules of the society were read and considered. Happy the nation, we are told, that has no history. Happy the society, I would rejoin, that has no rules. If the rules of our society have in subsequent times kept us from dangers and extricated us from difficulties, they were in the eighteenth century the cause of much bitterness and unhappiness, and very nearly brought about the wreckage of the Institution whose interests they were intended to protect. The name that stands in the minute-book of the society in front of Lettsom's is that of Dr. Hulme, who, at the next meeting of the society, which was held on the following Wednesday, May 26th, was elected librarian, Edward Ford being appointed secretary. It was, moreover, then arranged that Lettsom should take the chair at the ensuing meeting.

You will think it proper, I am sure, that I should say something in passing about the man whose name is found in our minute books in front of that of Lettsom—the man who was picked out to watch over the establishment of the Library, which, as was always intended, should constitute a very important element in our Society. Nathaniel Hulme was a Yorkshireman, who, at the age of twenty-three years, entered the Royal Navy as a surgeon's mate. Eventually, he took his degree in Medicine at the University of Edinburgh, sending in as his thesis an account of a disease which, unfortunately, he must have had ample opportunities of studying—scurvy. In connexion with this, he showed the benefits of lime-juice in long sea voyages. When he retired from the navy, Lord Sandhurst, who was then the First Lord of the Admiralty, secured for him the appointment of Physician to the Charter House. He went to live, therefore, in Charter House-square, where he enjoyed an extensive and an honourable practice. Unfortunately, in March 1807, an equinoctial gale blew over, or, as I suppose, he, in nautical language would have expressed it, "carried away" one of his chimney pots. It was nothing phenomenal as a gale, nothing like one of those gales to which he had been accustomed when afloat, and I can find no mention of it in the meteorological records of the time in the *Gentleman's Magazine*, but the illustrious physician and Fellow of the Royal Society thought it necessary to go aloft to see exactly what damage had been done. Getting up to the roof, he lost his balance and fell, receiving such serious injuries that he survived his fall only a few days. He had served the Medical Society well, as he had served his country; and we read in a contemporary biographical notice of him that he did "valuable work." He proved himself worthy of the place which he holds in our records, but from his calamitous fall we may, I think, enforce this obvious precept—that a physician should content himself with his proper sphere of practice.

A Society with a chairman, a librarian, and a secretary must needs find a home, and with this important business Lettsom was intrusted. The meeting-room was to be "as nearly central to the respective members as possible," so the Queen's Arms Tavern in Newgate-street was suggested. A good many members of our profession at the present day make their start in active life anxious, because they hamper themselves with a needlessly heavy house-rent. There was to be no mistake of that sort with our budding Society. Lettsom was to hire a room for a sum "not exceeding ten guineas a year." The "Queen's Arms" business fell through, for at the next meeting, Hulme and Lettsom were authorised to try to secure a vacant room in Wardrobe-court; and because a good many new men were joining the Society, the amount to be allowed for the annual rent went up with a bound to £15. With so much money at stake they thought it expedient to appoint a treasurer. And in choosing Lettsom for this office our founders made—as doubtless they knew they were making—an excellent selection. For the "Accompts book" and the minute books show that his purse as well as his hearty and efficient services were always at the disposal of the society.

From May 31st the Members did not come together again until nearly the middle of July, probably because they had not acquired a place for meeting in; but when they then met we find their minds exercised by the same three questions—the acquisition of a room, the formation of a library, and the drawing up of the rules. The Society was not two months old when Lettsom, the treasurer, laid the foundation of our library by giving "Percivall's Medical Observations" and the "Medicinal Education of Children." The title of the latter book is equivocal. Probably the "medicinal education" of children referred to the fact that, as people in those days had to swallow an enormous amount of filthy physic, they could not expect to survive unless their medicinal education were begun in very early life. I have not seen the book, for had I asked Mr. Hall to look it up for me, I might have been deprived of the opportunity of speculating as to the real meaning of its title. At this same July meeting twenty-nine new members were elected, amongst whom were Dr. James Sims, who a short time afterwards began his reign of twenty-two years in the presidential chair, and Dr. John Millar, who, at the next meeting of the Society was elected its first President. This selection, however, did not prove a happy one. Lettsom was not appointed the first President for, I think, two reasons—first, because he did not want to have himself thrust forwards in the society which he had done so much to establish, and secondly, because he already held the very important post of treasurer.

On Aug. 10th the sixth meeting of the society took place, and as Millar's name is at the top of the list of those present he doubtless occupied for the first time our presidential chair. Lettsom at once reported that he had set to work buying books for the library, for which the society thanked him and ordered his re-imbursement. The "Accompts book" shows that he had already spent £16 14*s.* in books. At this time the primary cleavage of the society into three parts was established by the appointment of three standing committees of reference—one of three physicians, one of three surgeons, and one of three apothecaries. And by way of further emphasis, as applications for membership were coming in at a great pace, the society resolved that for the present the number of its members should be limited to thirty physicians, thirty surgeons, and thirty general practitioners or, in the language of the time, apothecaries. It can scarcely be altogether a matter of surprise, though it may be of regret, if with the vast increase of learning which has taken place in our profession—without, I suppose, a proportionate increase of mental vigour and power of endurance—secondary and tertiary cleavages have since appeared in our midst. Thus, every region, organ, and tissue in the body has in turn been "specialised," from epiblast to hypoblast, and back again. But this process has surely now gone far enough—some would think too far. For it frequently happens that the practitioner who is cultivating his little allotment of epiblast, for instance, deems himself unable or unwise to look through a mere basement membrane to see what morbid changes may by chance be taking place in the adjacent, but not less important, plot, which his neighbour is cultivating in the mesoblast. So it has come about that one practitioner has been daily and diligently dealing with a tuberculous patch in a larynx, and refusing all the while to recognise the fact that his trusting and hopeful patient was dying of pulmonary consumption. And that another practitioner has been lumbering up the weak back of a growing girl with what he was pleased to call a "spinal support," when all that she needed was sunlight, fresh air, exercise, and freedom. Everybody here must feel that I am not erring upon the side of exaggeration in making these remarks. And if such things have happened in the past, what is going to happen in the future? A large proportion of special practitioners of the present time are fortunately under the inhibitory influence of broad principles which they have acquired in the useful preliminary work of general

Hosted by Google

medicine, general surgery, or general practice. But henceforth, it seems, the youthful practitioner is to embark in the cultivation of some speciality before the ink on his diploma is actually dry—at any rate, before blue ink has had time to turn black. We hear it urged that the public like this sort of thing. I must not stay to discuss that statement, or even to deny its truth. But supposing that the public do like it, is that a reason why we should stand quietly by whilst our profession, as practised by Hulme and Lettsom, is brought down to the level of persons who try to nourish their children upon patent foods and themselves upon quack medicines?

As I have said, our society was originally designed to secure the collective experience of the three primary divisions of the profession. As a result of this arrangement it would be impossible, I think, to name any other society in which the discussions and debates are more generally instructive; and I make no empty boast when I say that though our society is well advanced in its second century, its work is still abreast with the times. Though it occupies itself with micro-organisms of all sorts it is not consumed by them, and though it investigates antiseptics it does not smell of them. It discusses drugs without exciting nausea, and it enters into pathological problems without becoming morbid. It is scientific without overbearance, and it is never dull. At least, not often. Our founders wished us to be cheerful; and so we are, without effort.

JOHN FOTHERGILL.

Though John Fothergill is one of the Patron Saints of the Medical Society of London, he was never one of its Fellows. He was not, as has been erroneously stated, "one of our founders." The veneration in which he is held by us is chiefly due to the fact that he was the dear friend of our Lettsom, and, during the first ten years of his professional life in London, his guardian angel. Lettsom said of him: "My medical creation was his, and my success in life the result." We esteem him also because he was "one of the first physicians of the age." This was Lettsom's estimate of his professional position, and, looking through contemporary medical literature, it seemed to be a just one. He was, moreover, a man of immense learning and information. He apparently knew all that was known at that time in the natural sciences. His botanical garden at Upton, near Stratford, was celebrated throughout Europe and America. He had fifteen men constantly at work in it and there were other persons employed in making drawings for him of its trees, plants, flowers, and fruits. He was a Fellow of the Linnean Society, and was reckoned to be one of the chief authorities of the day upon shells and corals. He was a considerable chemist, and he was a judge in matters of Art, and it is not unlikely that his young friend Lettsom acquired from him the insatiable thirst for collecting. John Fothergill was a member of the Medical Society of Edinburgh, and in 1776, when a medical society was being founded in Paris by the King of France, he was one of a select number of foreign physicians whom the society thought proper to honour with their diploma. Feeling as we do towards Fothergill, we cannot but regret, as we look back, that he was not a Fellow of our Society. But Fothergill was not a man to do things by halves, and probably Lettsom deemed it unkind to attempt to enlist his help at the foundation of the society, busy man that he was. It must be remembered that as at that time, 1773, Fothergill was in his sixty-second year and overburdened with private practice, that as he had a mansion as well as that enormous garden at Upton and a country seat near Warrington, and that as his hands were full of, and running over with, philanthropic schemes of all sorts, he could hardly have had any time to devote to launching a medical society. As a matter of fact, he could rarely steal away to his house and grounds at Upton, and often, when he did get there, it was so late at night that the only way which he could obtain enjoyment and profit out of the garden was with the help of a lantern. Lettsom, however, was at that time under thirty years of age. He was full of energy, and he had, it is to be surmised, sufficient leisure.

Doubtless Lettsom told his friend of all that was going on in connexion with the beginnings of our society, seeking and obtaining his advice and, I think, acting upon it. There was no better man to go to for advice in the matter than Fothergill, as he had great practical experience in the working of a society of physicians of which he and William Hunter were the leading spirits. (Of this society I shall have a good deal to say shortly.) But here Fothergill's interest in the Medical Society of London must have ended. In the "Cash-Accompts Book" of the society from its foundation to the beginning of the nineteen century, in which are found the names of all those paying their entrance fees and subscriptions, the name of John Fothergill is conspicuously absent. The circumstantial evidence which this book supplies in support of my statement that he was never a Fellow of our society is incapable of refutation. For the unearthing of this valuable book, as for much else in the preparation of this Oration, I am indebted to Mr. Hall, the Registrar of our society. In the early minute books of the society and of the council the name of John Fothergill does not appear as a Fellow, nor can I find that he ever attended as a visitor. Fothergill had an enlarged prostate, to which, as I learn from the pages of the *Gentleman's Magazine*, he gave neither attention nor consideration. But nature is jealous; and in the year 1772, when he was only sixty-one years old, he began to break up. He had just lost his younger brother, Samuel, the celebrated preacher, and he said, in his bodily distress and in his sorrow, "Our health is no more at our command than length of days. Mine seems drawing fast to a conclusion. Though painful my nights and wearisome my days, yet I am preserved in patience and resignation." Next year—the year of the foundation of our society—he was "much oppressed"; but he said that he hoped to follow in the steps of his dear brother through what he called "the remains of this life." It would not, therefore, have been a friendly act had Lettsom tried to induce him even to lend his name to the new society.

There is another matter in connexion with Fothergill to which I wish to refer. Some of his biographers state that he died from "suppression of urine." Lettsom himself says it, but the statement is incorrect. Alluding to the fatal illness of December, 1780, he says: "He was again seized with a suppression of urine, which no art could remove." But in that he speaks of his being on that occasion "as serene as in perfect health," he obviously could not have meant that Fothergill was the subject of what we understand by "suppression of urine." Alluding to a similar attack which the patient had undergone just two years previously, Lettsom wrote that on waking out of a short sleep his illustrious friend was attacked with a forcible inclination to make water, but without the power. "At length," he writes, "a total suppression came on that required manual assistance for two weeks, which was sometimes accompanied with excruciating pain. ..... In the height of his distress I visited him and found him calm and collected." Without doubt someone (not Lettsom) was trying to relieve him from time to time with a catheter, and with greater vigour than success. There was some "suppression" in connexion with Fothergill's fatal illness—not of urine, but of an important clinical detail. Somehow or other Lettsom omitted to say in his memoir that after death two quarts of urine were found in the poor physician's bladder. This interesting piece of information I discovered in the *Gentleman's Magazine* for 1781.

How has it come about, in spite of the absence of any evidence in that direction, that John Fothergill has so generally been considered to have been one of the fathers of our society? If we turn to the "Memoirs of Fothergill," by Lettsom, we find a heading to the effect that they were "read before the Medical Society of London, July 17th, and October 23rd, 1782." Why, it might well be asked, should Lettsom have read those Memoirs before our society if Fothergill had no connexion with it? The answer is that though Lettsom read the well-known Memoirs "before the Medical Society of London," he did not read them before *our society*, which was then meeting on the first Tuesday of every month, as recommended in February, 1781. In 1782 our society met on July 2nd and Oct. 1st. July 17th and Oct. 23rd, the days when Lettsom read the Memoirs, were Wednesdays. About the middle of the eighteenth century some physicians in London agreed to meet together for their mutual improvement in the practice of their profession. They were either such as had the care of hospitals, or, to quote their own words, "were otherwise in some degree of repute in their profession." When these meetings had continued a considerable time, some of the members (Fothergill amongst them) decided to publish their proceedings. So, "with some other physicians," they formed themselves into a society for collecting and publishing "Medical Observations and Inquiries." They regarded it as a reflection on the Faculty that no attempts of that kind had hitherto been

Hosted by Google

made in London. The first volume appeared in 1757.[1] These eighteenth century physicians were not only persons "in some degree of repute," but also of prosaic common sense, for they said in their preface that they did not want papers the chief tendency of which was "to show the parts and erudition of the writer." They also said that they did not intend to publish all the papers which might be sent in to them, but that useful observations, described with clearness and candour, would be "thankfully received." They particularly asked for notes of unsuccessful cases, and for "accounts of errors in the cure of diseases." Concerning the question of "errors in the cure of diseases" I will not venture to make any remarks, my practice being confined entirely to surgery; but I cannot refrain from expressing my strong approval of their desire to have notes of unsuccessful cases. A hundred years hence, or in less time than that, when the practitioner in the few diseases which are left for him to treat takes down from their dusty shelves the volumes containing the reports of our societies, and the records of our treatment, he will say, "These men at the end of the nineteenth century were not void of dishonesty. They wrote and talked as if all their patients got well, but we know that they did not. They seem to have carved the records of their successful cases upon the rocks, but if ever they thought of their failures, the utmost that they did was to scratch them upon the sands of the sea at low-water mark." Would it not be a good thing if our society set apart one or two evenings in each session for the discussion of unsuccessful cases and of those which have ended in disaster? They should be called "confessional evenings," and I am sure that they would be well attended. There should be no reporters present, and I believe that a good many of our Fellows would take part in the debates, even though their remarks would not appear in the forthcoming number of THE LANCET. What pleasant evenings could be spent in discussing the hideous mistakes of other people! If anyone asks if I would contribute to such "confessional evenings," I would venture to remind the society that a few years ago I thought it my duty to bring forward the report of a case in which, to my extreme sorrow, a misadventure on my part brought a simple operation to a fatal conclusion I am speaking, therefore, from sad experience when I say that such a course is right and proper. And I will also say this, that there is no society in London where the candid confession of practical error would be more faithfully or sympathetically received. The venerable age of the Medical Society of London has happily brought with it a kindly and paternal spirit which has come down as a precious heritage from Lettsom, and through him from Fothergill, so that we, its children, are able to look up to it not only with respect but affection. I cannot but think that it would be well for the aggressive spirit of modern methods to wrap itself in a sheet from time to time, to acknowledge that it is not yet infallible, and here to be shriven. That our founders intended to have authority amongst the Fellows and to exercise it, sometimes with severity and sometimes with gentleness, but always with impartiality, is evident to any one who reads the records of their early doings. And it is not without significance that *the very first disbursement* which they made on behalf of the society, on May 27th, 1773, was a sum of five shillings for a hammer.

Let me now return to the Society of Hospital Physicians—of physicians in some degree of repute, and of "others," who were to receive, consider, and possibly publish the medical observations which might be sent in to them. They worked diligently and, happily, without ostentation—two excellent qualifications for solidity and success. It was on behalf of this society that Fothergill burdened himself with collective investigation concerning the epidemic of influenza as it appeared in various parts of the country towards the end of the year 1775. This labour was duly acknowledged in the sixth volume of their "Observations," which they published in 1784. They say that from the materials collected by Fothergill from the faculty at large, and from his own sketch, he had intended to form a complete history of the disease, but that that which his sudden decease in 1780 prevented him performing the society "endeavoured to accomplish." "Indeed," continues the preface, "considering the not unfrequent return of this epidemic, how troublesome it was to most, how it affected many with lasting debility, and, though not dangerous in itself, how it accelerated the fatality of dangerous distempers, it deservedly becomes an object of serious inquiry to the faculty." Within two years of Fothergill's death—namely, in 1782—this pestilence was again upon them with unabated vigour; and as it concerned "the Medical Society of London in the eighteenth century" I shall have occasion to refer to it later. Just now, however, I am, or ought to be, explaining how it is that Fothergill has so generally been considered a Fellow of our society.

Fothergill had sent printed circulars to medical men in town and country with the view of working out a better understanding of the disease, and the replies to it, which are published in the volume, show that in many respects it closely resembled the influenza of the present time. I personally have had a greater experience of influenza than most medical men. But lest I might be considered by this statement to have wandered out of the narrow paths of surgical practice, and even into the realms of boastfulness and arrogance, I hasten to explain that what I mean is that I have been attacked by the disease far more often than I desired, and I think, speaking at any rate from an actuarial point of view, than I deserved. Justice was, indeed, blind in wasting upon me, a surgeon, a personal experience in influenza which might have been useful in the establishment of a physician. However, my experience of the disease has rendered my study of it in these old volumes of more than an antiquarian interest. The replies which Fothergill received gave a graphic description of the suddenness of the onset of the disease; of the pains in the head, back and limbs; of the foul tongue, the loss of taste, and of appetite and of sleep; of the soreness of the wind-pipe; of the dejection of spirits, and of the terrible debility. The well-known Dr. Cuming said that in Dorsetshire, in many gentlemen's families, not one servant was free from the disorder. Horses and dogs, moreover, were affected by it. Worse than all, the horrors of the influenza of the eighteenth century must have been actually increased by treatment, for physicians and patients seemed alike under the influence of a blind faith in venesection and nauseating drugs.

The Society of Physicians met every month, and Elliott tells us that Fothergill was rarely absent from the meetings. As I have already said, John Fothergill and William Hunter were prominent members of this mutual improvement society, to which in 1756, in the ordinary course of business, Fothergill read a paper which, in the table of contents which followed the preface to this volume, is described as being "communicated to the Medical Society." This Society of Physicians was, of course, a medical society but it was not The Medical Society of London. No, Fothergill's medical society was twenty years older than Lettsom's. Lettsom was a member of Fothergill's society; but Fothergill was not a Fellow of Lettsom's society.

Fothergill was president of his society at the time of his death, 1780, and the members naturally called upon his intimate friend and their fellow-member, Lettsom, for a memoir of him. It will be noticed in the bold heading of this memoir that though Fothergill's society is called the Medical Society of London, the words "the" and "of" are not spelt with capital letters as they should have been if they had referred to The Medical Society of London, which obviously they did not do.

There is a verse in the First Book of Kings which might almost have been written of Fothergill: "And he spake of trees, from the cedar tree that is in Lebanon even to the hyssop that springeth out of the wall. He also spake of beasts, and of fowl, and of creeping things, and of fishes." But Fothergill did not regard the vegetable and animal kingdom merely from the point of view of the biologist. Though his interest in them was certainly scientific it was also strongly utilitarian—and particularly with reference to materia medica and foods. Thus, in 1767 he spent a considerable sum of money in connexion with a scheme which should enable the poor and the middle ranks of housekeepers to purchase fish at a low rate in London. In the same manner he set to work to have potatoes which had been bought cheap in Lancashire brought up to town by water. It would take a stronger man than the gentle Fothergill, I fear, to break up the "fish ring." We are told—I know not with what truth—that at the present time wholesale dealers would at times rather destroy fish at the seaside than send it to the great cities where it could be sold at a cheap rate. Such a monstrous act would

[1] Medical Observations and Inquiries, by a Society of Physicians in London, 1757.

Hosted by Google

be to rob the poor; and the day may not be far distant when it will be punished as a crime.

I suppose that one great cause of the spread of the erroneous belief that Fothergill was a Fellow of our society, is due to a sentence which occurs in Pettigrew's "Life of Lettsom"—a work to which anyone would naturally refer who was specially interested in the early doings of this society. On pages 86 and 87 of the first volume he writes: "Dr. Fothergill was, at the time of his decease, the President of the Medical Society of London, at whose meetings papers and other communications on medical subjects were read or made. Many of these were furnished by Dr. Fothergill, and the members felt desirous of having some account of his life submitted to them. Accordingly, Dr. Lettsom was requested to draw up the memoir." I cannot understand how Pettigrew came to make such a slip. It seems the more inexcusable in him as he was not only a Fellow, but also the Registrar of our old society. Although he was writing a life of Lettsom, and not of Fothergill, his mention of Fothergill ought to have been made with accuracy. And though the date of his writing was in the thirty-seventh year after Fothergill's death, it would have been quite easy for him to verify the truth of his statement. Probably he had been misled by the wording which appeared at the head of Lettsom's memoir. But if we cannot hold Pettigrew excused for the error of making John Fothergill a Fellow of our society, what is to be said when Dr. Munk, a Fellow of the Royal College of Physicians and the illustrious medical biographer, falls into it? In his account of the life of William Hunter, in the "Roll of the Royal College of Physicians," he says: "On the death of Dr. Fothergill, Dr. Hunter was unanimously elected president of the Medical Society of London." Dr. Munk also failed to distinguish the Society of Physicians, of which John Fothergill and William Hunter were the leading spirits, from the Medical Society of London.

DR. LETTSOM.

For every Fellow of this society the name of Lettsom has a charm, and although he may not be acquainted with the details of the private and professional life of this gentle Quaker practitioner he cannot be much within these walls without becoming influenced—he may not know exactly how or why—by unconscious memory of him.

> "The evil that men do lives after them;
> The good is oft interred with their bones."

But so was it not with Lettsom. The more closely his history is studied the stronger does the feeling grow that he was a man to be revered. He certainly has left no evil influences behind him, and it was not possible that all the good he did could be interred with his hallowed bones. It is no empty phrase to say that the world is all the better for the fact of Lettsom having lived. Certain is it, moreover, that our profession has benefited by his life and example. And as for the Medical Society of London, if it is not wholly indebted to him for its conception and creation, it is at least greatly indebted to him for its preservation and for much of the success and respect which has attended it throughout its long and eventful life. There was no self-seeking about Lettsom—no vaulting ambition; his chief thought was for the happiness of others, and wherever he went he was doing good. Pettigrew truly said of him that to detail his useful career is to pronounce his highest eulogy.

John Coakley Lettsom was born in the West Indies in 1774. He was one of twin boys, and, previous to his birth, his mother had six times had twin boys. He was educated in Lancashire, and soon after his sixteenth birthday he was sent as an apprentice to Abraham Sutcliff, a surgeon apothecary at Settle, a dull little town at the top of Ribblesdale. About the second year of his apprenticeship Lettsom began to visit patients. Pettigrew says, with a sigh as it were, that he doubts if he was then quite fitted for that particular work, as he had never attended a lecture or seen any anatomical figure except a skeleton. The old apprenticeship system encouraged this sort of thing, and it proved the ruin of many a would-be medical man, casting him adrift with a thin veneer of practical information upon a foundation of solid ignorance. But it did not spoil young Lettsom, who kept on steadily working at natural science and languages as well as at his profession. At the end of his five years' apprenticeship he came to London, where he did not know a soul. But he brought letters to Fothergill, who was then fifty-four years old, Lettsom being his junior by thirty-two years. It is well to keep in mind the fact that Fothergill was thirty-two years older than Lettsom, for as the acquaintance between these men ripens into deepest friendship, and we see them side by side, this is practically the only difference that we find between them.

Probably the chief object of Lettsom's journey southwards was that he might advance his professional knowledge by practical work in the wards of a hospital, for London was then, as it still is, the finest field for clinical work in the British Isles. Then, as now, however, by some absurd miscarriage, the well-skilled practitioner who desired to obtain a degree in medicine had to go elsewhere for it. Lettsom went to Leyden for his. Had he lived at the present day he might possibly have gone to another friendly kingdom and secured for himself a Doctorate with dispatch and "with distinction." I do not mean by this that the medical man who has been educated in London acts unwisely in going abroad for a degree in medicine. On the contrary, I commend his prudence, for a degree in medicine—no matter whence it comes—is of real practical value. What I wish to emphasise is the strange anomaly that in this vast metropolis, second to none in clinical wealth and educational advantages, there should not be a degree in medicine obtainable by the general run of students. The result is that London as a teaching centre is being deserted and its clinical advantages ignored, in order that students may undergo their medical training in other cities, and in towns, where they are able to secure the title of M.D. as a fitting reward for diligent work.

Young Lettsom saw a great deal of Fothergill, whose professional position and success fired him with the ambition to establish himself in London. But he had no money. In twelve months the small store that he had brought was exhausted, so he packed his ambition in his trunk and set sail for Tortola in order to take possession of the little property left him by his father. This consisted of a small portion of land and about fifty slaves. At that time, says his friend Pettigrew, he was not possessed of £50 in the world; but he at once set his slaves free, and by so doing became a voluntary pauper at the age of twenty-three years. He did not take this step because he was so advised or because it seemed "advisable," but because he could not tolerate the idea of trafficking in human blood and because, as Pettigrew says, he thought it right to do unto others as we would wish they should do unto us. This, in brief, was Lettsom's religion, as also it was the sum and substance of the teaching of the Great Physician in whose step he humbly tried to walk.

Gentlemen, at the present moment we have urgent need of another Lettsom to set free slaves; and I say with sorrow that these slaves are members of our profession—medical brethren who, unable or unwilling to engage successfully in its honourable practice, have sold their birthright, their art, and their independence to trading clubs, called medical aid societies. It is not for me to enter with ungenerous detail into the actions of brethren thus enslaved. Possibly, indeed, had I been placed in similar circumstances I might have entered into the same servitude. But of this I am certain, that, had I done so, I should long to be released from it! And so, surely, do they. The question is, How is their freedom to be secured at the earliest possible moment? Many years ago there lived in Mantua a family medical attendant who found it difficult to make both ends meet. What his name and qualifications were we have not been told; he is simply called "an apothecary," which, as I just now remarked, was in former days the title of the general practitioner. Nor does it transpire why he had proved a failure in practice; but from representations which we have had of him upon the stage I think that he must have been lacking in that essential for success in family work, "a good bedside manner." A broken-hearted lover wanted to buy some poison from him, but he had qualms about selling it. Qualms are conscientious objections which yield to opportunism, so, without needless waste of time, the apothecary handed over the poison, remarking, as he did so, that his poverty but not his will consented. I suppose that the medical men who have entered into the slavery of the trading medical associations would make the same unctuous remark. At least, I understand that when one of them is asked by a brother practitioner, whom by the acts of his association he is helping to ruin, if he approves of such acts, he rejoins, in shame and degradation, "What am I to do?" And at the same time he shrugs his shoulders, as if to imply that, though a slave, he has not lost all sense of honour—that at least his will did not consent. All the same, he is in the pay of those who are sending round male and female touts—agents they are called—whose business it is

Hosted by Google

to undermine the practice and steal the patients of his brother practitioner. If, when doing this, they smirch his reputation and reduce to the level of paupers those who had hitherto been able and willing to pay him adequately for professional services, what is that to them? Let the galled jade wince, their withers are unwrung.

These trading medical associations are sometimes also life-insurance companies, which endeavour to attract insurers by offering the collateral advantage of gratuitous medical attendance by the practitioners whom they are "sweating." Probably the directors of these companies have already found that plan to give good results in their daily work, when, as pushing grocers, they throw in a present of sugar to each purchaser of a pound of tea.

Note how skilfully the immortal playwright managed that scene in Mantua. He has got rid of Balthasar, who had brought the love-stricken Romeo the news of the supposed death of the lady, as his presence might possibly have interfered with the conclusion of the nefarious bargain by the apothecary. Certainly if Friar Laurence, or any other strong man, had been about, the lover would never have dared to make the tempting proposal to the pliable practitioner. It would not have been necessary to say to the apothecary that such an act would be unworthy "in a professional sense"; a mere shake of the head would have been enough to stop it altogether. Anything more discreditable to the honour of our profession than this commercial compact with medical associations it would, I should think, be difficult to imagine. It is disgraceful in a professional sense, and should have been stopped long since. A mere gesture of disapproval on the part of the head of our profession would have checked its inception. And where, it is asked, is our stern though paternal Friar Laurance, the guardian of the registered practitioner and the keeper of our professional honour? Where, all this time, is the General Medical Council? It may be that though individual members of that Council have possibly heard rumours of the existence of the discreditable alliance between Art and trade, their attention has never been officially called to it, or their powerful and much needed aid invoked. Here, therefore, from the chair of the Orator of the Medical Society of London, a chair which Lettsom the Liberator occupied on no less than three occasions, I beg leave to proclaim to the General Medical Council the existence of the abuse and to appeal to them to "come over and help us."

The West Indies must have been more prosperous one hundred and thirty years ago than they are to-day, for, starting in practice in the small island of Tortola, Lettsom made nearly £2000 in five months. Half of this he gave to his mother; the rest he placed with his ambition and came back to London with the view of following in the wake of Fothergill. Even at the present time a young man who is fired with an ambition to practise as a consultant in London might do worse than follow the example of Lettsom with respect to a certain delicate matter. He had probably thought it well out, for Pettigrew says: "He determined upon forming a matrimonial connexion with an amiable young lady, the daughter of a wealthy tin-plate worker." The union turned out an extremely happy one, so that we may assume that though the gentle Quaker happened to marry where money was he did not marry for money. Such an act, indeed, would have been entirely foreign to his nature.

A few words about the death of Lettsom shall close this short notice of him. The manner of his death should act as a warning to us; it was as follows. For some time he had been attending a gentleman whose case proved fatal and he was desirous that the body should be examined. The necropsy was chiefly made by himself on Oct. 22nd, 1815. He remained in the cold room for two hours, and on the next day he felt chilly and unwell. Then strong rigors came on, with fever and with severe pains in the arms. He suffered intensely and, becoming delirious, sank exhausted on Nov. 1st. Making a post-mortem examination in a private house is usually a depressing and chilling business. The window is partly open and there is no fire in the grate. And when on a late October day a man seventy-one years of age, probably with his coat off, spends two hours in the cold room, what wonder if he contracts a "chill"? He probably absorbed a large dose of septic material. Lettsom diagnosed his fatal illness as "rheumatic." Septic diseases were not as well understood then as they are now, and even at the present time they are not infrequently regarded as "rheumatic." Probably the patient whose body the earnest physician was examining had died from some obscure septic disease. That Lettsom was not clear as to its nature is evident, I think, from his spending so much time at the necropsy.

A LOYAL ADDRESS.

A Resolution of the Council of the Medical Society of April 3rd, 1789, is especially interesting to us to-day in that it expressed the desire of presenting an Address to His Majesty on his happy recovery. For carrying out this resolution special meetings of the Council and the society were held, the Address was duly sent up, and at a subsequent meeting it was resolved that Lord Sydney's reply on behalf of His Majesty be inserted on the minutes. To say that this summer of rejoicing, 1897, finds the Medical Society of London still loyal is feebly to express the feeling of its Fellows, for "that fierce light" which has beat upon the Throne throughout the last sixty years has been reflected straight into the hearts of Her Majesty's subjects, turning *loyalty* into *love*.

THE MEDALS.

John Fothergill died when the Medical Society of London was seven years old, he being then in his sixty-ninth year. Lettsom, as we know, felt his loss very keenly, and four years after his death he wrote to the society as follows:—

> "GENTLEMEN,—To preserve the memory of illustrious characters by some permanent memorial is not only grateful to the friends of the deceased, but excites in the living that commendable emulation which leads to great and virtuous actions. Such were those which will render dear to distant posterity the name of Dr. John Fothergill, in memory of whom I have ordered a medal to be struck, under the patronage and at the disposal of the Medical Society of London, held in Crane Court, Fleet Street. It will be in gold, of ten guineas' value, to be called the Fothergillian Medal, and to be given annually on the 8th day of March[a] to the author of the best Essay upon a Prize-Question proposed by the Society," &c., &c.
>
> "JOHN COAKLEY LETTSOM."

The date of the letter, May 25th, 1784, is interesting from the fact that on that very day Lettsom had been reading to the society a clinical report of the case of Dr. Fothergill, for which he had received the usual thanks. The preparation, or the reading of this paper, or the reception which it got at the society, had doubtless filled his heart with recollections of his dear friend, and with a burning desire that time should not be allowed to completely efface the fading memory of so good a man. The letter was read at a general meeting on Thursday, June 4th, 1784 (although Tuesday was the proper meeting day), and a vote of thanks was unanimously passed to Lettsom for his generous offer. In the following week the society again met, and a committee was appointed to consider the design, and a plan for the distribution of the medal.

Within a fortnight the committee brought in their report; they proposed that the obverse of the medal should contain the head of Dr. Fothergill with this legend: "Fothergillius, Medicus, Amicus, Homo," together with the date of his birth and death, and that the reverse should exhibit Hygeia, holding in her right hand a wreath to crown the successful candidate, who is presented by Esculapius, together with certain letters which briefly indicated that the medal was the gift of the Medical Society of London, which was instituted in 1773. This design seems somewhat ambitious; and I think that when it was shown to Louis Pingo, the artist who was to engrave the die, he must have told the committee that the order was rather too extensive for satisfactory execution. I should think that even Benvenuto Cellini himself would have stood aghast at the proposal. It is to be noticed that Lettsom said nothing in his letter about investing a sum of money to defray the annual expense of the medal, and the society raised no question upon that point. He simply said: "I have ordered a medal to be struck." But inasmuch as the details were subsequently to be arranged by a committee, he could not then have actually given the order for the striking of the medal. Indeed, the design which he and the other members of the medal committee proposed was not in the end adopted. The medal, as eventually struck, is thus described by Mr. Grueber from the specimen in the British Museum:—Obverse: Bust of Fothergill to right, in wig and close-buttoned coat. Legend,

[a] The birthday of Fothergill.

Hosted by Google

Johannes Fothergill, Medicus Egregius, Amicis Carus, Omnium Amicus. Reverse: Within laurel leaves, in which are entwined two serpents, *Medicinæ et Scientiæ Naturalis incremento.* Above, *Don. Soc Med. An. Salut. 1773. Instit.*

Thus the design proposed by the committee had been considerably tamed down and, I think, improved, before the die was engraved. I have the pleasure of showing a replica of the original John Fothergill medal. Mr. Grueber's description omits to state that the dates of the birth and of the death of Fothergill are given upon the rim of the medal. So far as I can ascertain, only seven examples of this medal were ever struck in gold, one of which was presented to King George the Third as a specimen; this is now in the British Museum. One was awarded in 1787 to Dr. Falconer of Bath, and three years later one to Dr. Willan, the dermatologist. In 1791 Lettsom himself had the pleasure of receiving one for his prize dissertation. Mason Good and Bouttatz received medals in 1795 and 1801 respectively, and in 1803 Edward Jenner was awarded the seventh and last.

It is the custom, I believe, in certain societies (not medical) for each individual to break into a thousand pieces the glass out of which some toast has been drunk which is specially dear to the hearts of those present, so that by no possibility can the glass which has been thus honoured be submitted to desecration. Extravagant as the custom may seem, there is a beautiful sentiment underlying it. As we look back it is with considerable satisfaction that we learn that our illustrious colleague, Edward Jenner, was the last recipient of Lettsom's Fothergillian gold medal—Jenner the greatest benefactor of the human race that ever lived. After this it is well that we hear nothing of medals subsequently struck from that die. By honouring Jenner it had fully honoured the society, and had brought its work to a splendid close. But, gentlemen, if that die were yet in existence we could show upon our roll of Fellows the name of one for whom it might still be struck upon purest gold—of one who, second only to Jenner, has been a benefactor of the human race. Need I say that I refer to Joseph Lister?

The first gold medal, then, was obtained by Dr. Falconer in 1787, and at the society's meeting on April 9th of that year a letter was read from him saying that he would be up in London in the following June in order to receive it. Thereupon, "Dr. Lettsom was appointed to deliver him the Fothergillian Medal in form." On Friday, June 1st, there was a small meeting of the society, at which Falconer took his seat as a corresponding member, but the only business recorded is the decision that the presentation of the medal should be postponed for eight days—namely, until Saturday, the 9th. There was a very good reason for delaying the presentation of the medal—the society had not yet received it from the unbusiness-like artist. On Monday evening, June 4th, a meeting of the society was held in the ordinary way, and a good deal of business was done at it. Falconer, who was present, must have been impressed with the energy and prosperity of the society. But he and everyone else must have felt sympathy with Lettsom in that the Fothergillian business was hanging fire. Here is an extract from the minutes for that night:—

> "Dr. Lettsom informed the society that as, through the neglect of Pingo, who was entrusted with the execution of the Fothergillian medal, and has had it in his hands for upwards of a twelvemonth, there can be no probability of getting the medal out of his hands so soon as might be expected, so that it could be presented to Doctor Falconer on Saturday night, and Dr. Falconer having signified that his staying in town would be attended with inconvenience, it was proposed that Wednesday evening should be fixed on for the delivery of a *model* of the Fothergillian medal to Doctor Falconer, which proposal, being moved and seconded, was agreed to *nem. con.*, and the messenger was ordered to summon the members for Wednesday evening at the usual hour."

I make no apology for going into detail in connexion with the delivery, or rather the non-delivery of the first Fothergillian medal, for the account cannot fail to be of interest to every Fellow of this society. In accordance with the resolution just read, an extraordinary meeting was held on Wednesday, June 6th, 1787, one of the last meetings held at the society's house in Crane-court. There was a large attendance of members, and the meeting was honoured by the presence of upwards of fifty visitors. Dr. Sims duly stated from the chair the business for which the society was convened for that evening, and although it was an extraordinary meeting the minutes of the last meeting were read and confirmed, and also various other minutes which had reference to the institution of, and to regulations concerning, the Fothergillian medal. After signing the minutes the president left the chair in favour of Lettsom, who delivered an elaborate address, which at the beginning was metaphysical, and then, turning into a eulogium of Fothergill, ended with the apotheosis of Falconer. After this "he delivered publickly a model of the Fothergillian medal." Falconer replied, and then Sims resumed the presidential chair and moved a vote of thanks to Lettsom, not only for his address of that evening, but for the great interest, liberality, and assistance which he had always extended to the society. Falconer must have had plenty to think about as the stage-coach was taking him and his dummy medal down to Bath.

On March 12th, 1787, Dr. Sims moved a resolution to the effect that a silver medal bearing the same device with the Fothergillian medal "should be given annually by the Medical Society to the author of the best dissertation on any other medical subject." This was unanimously agreed to, "with a proviso that the ordinary members of this society shall not be allowed to be candidates for the said silver medal." Lettsom was at this meeting; doubtless he and Sims had talked it over beforehand. But I suppose that the members of the society objected to being cut out from all possibility of acquiring the silver medal; so we are informed in the preface to the second volume of the *Memoirs*, published in 1789, that there should be two silver medals adjudged annually, one to the author of the best essay read before the society within the year, written by a Fellow; the second for the best essay by any other person. A Fellow, I might remark, was any member of the society who resided within seven miles of London. Thus at the end of the eighteenth century our society was prepared to present annually one gold medal and two silver medals in the interests of the advancement of medical science.

THE MEMOIRS.

The volumes of memoirs which our society published in the eighteenth century are a mine of wealth, and many of the articles are written in a forcible and picturesque style which greatly adds to the pleasure of perusing them. Towards the end of the second volume, for instance, there is a long letter from Dr. Hamilton to Lettsom on the influenza which occurred in 1782. Here is a small piece of it. "Few diseases ever produced loss of strength more suddenly. The crew of the *Fly*, sloop-of-war, was an instance of this. The captain affirmed that forty of his men fell ill in less than eight hours, several of whom dropped down at the wheel as they steered the vessel. This circumstance obliged him to put back and stand again for the Yarmouth Roads, which he had left only a few hours before (with all hands apparently well), merely for want of hands to navigate her." In that terrible epidemic, as at the present day, influenza knocked down medical men with as little discrimination as it did their patients. Hamilton himself took it severely, dropping down at the "wheel, as it were." "But," said he, "the nature of my situation and the number I was obliged to visit prevented me from taking that care of myself which I recommended to others." There was no chance for him of "putting the ship back"; he was compelled to stand at the wheel even if he had to be lashed to it. And so it is with many a practitioner to-day. From no sordid motive, but from a sheer sense of duty, he goes his daily rounds attending people, many of whom are not feeling half as ill and miserable as he is himself. "It happened frequently in that epidemic," continues Hamilton, "that patients insisted on being bled; 'many were bled by my young man,' says a surgeon, without advice." The young man was, of course, the unqualified assistant of that day. In the advertisements of more recent times he called himself "a gentleman of experience, *sine diploma*"—as if that were actually a qualification for practice. He usually considered himself perfectly competent to treat a case of heart disease, though he might never have seen a mitral valve; to deal with an obscure injury to an elbow, though he had never dissected a joint; or to look after a man with Bright's disease, though he had never handled a test-tube or looked down a microscope. He plumed himself all the while on the fact that he was a "practical" man, and, strange to say, there were many patients who shared with him the good opinion which he had of himself. There was apparently only one professional act which he could not do, and that was to sign the death

Hosted by Google

certificates which considerable practice and familiarity enabled him to fill up with speculative precision. Fortunately, he is now a thing of the past, the General Council of Medical Education having sent him on a mission to minister to the necessities of the dodo and the great auk.

It is interesting to learn that when Dr. Hamilton took the influenza he declined to be bled. The grounds on which he excused himself from submitting to so orthodox a measure are worthy of study. "Besides," says he, "I am apt to think our constitutions are considerably changed this last century in Great Britain. Luxury, and its enervating effects," and so on, and so on. We hear the same croak at the present day. "Our constitutions are changed," and of course for the worse. "Men are not what they were; it was just the same in Ancient Rome," and stuff of this sort. Before we need pay any heed to such rubbish we must forget what Britishers and Irishmen have done in recent years; how they were tried by, but triumphed over, the severities of Crimean cold; the scorching horrors of a mutinous India; the fatigues of forced marching in wild Afghanistan; and, yet later, the difficulties which nature herself had strewed in the pathless route that brought them to the glorious relief of Chitral.

Reading, or merely glancing through, the early records of this society one cannot but be struck with the earnest and practical nature of the communications, with the width of the range which they cover, and with the fact that they were made in almost equal share by the three classes of its Fellows. From the first this has been to the great and manifest advantage of our society, and may this arrangement long continue. During the time that, in various ways, I have been concerned in the affairs of the society I have noticed, I am glad to say, but little indication of a desire to leave the old and the good for the sake of the new, but not necessarily the better. I must confess, however, that it was lately a bitter grief to me to see our ancient presidential chair of mahogany replaced by a modern one of maple. But this our meeting-room has been rendered so increasingly attractive and comfortable by a somewhat rapid evolution that I am quite willing to admit that those who differed from me on that occasion were not irrational. Further than this, however, I will not go. But while I am upon the question of our furniture, I would like to ask how it is that our worthy president is not wearing the cocked hat, without which our early presidents did not consider themselves respectfully attired? The first "Accompts book" shows that for a "hat for the president" we paid £2 10*s*. Why, I would ask, is that hat not in evidence to-night? In Medley's great picture of a meeting of the society the old cocked hat is duly represented.

The shortness of the time allotted for an oration has prevented my touching upon many important incidents in the history of the Medical Society of London in the eighteenth century. I have not been able, for instance, to refer to the battles which took place over the drawing up of the rules or to the exciting occasion when the society found itself locked out of its own rooms. Nor to the gentleness and wisdom which Lettsom showed as he helped—to use the words in the minute book—to establish the society upon a basis of permanence and dignity. But all these things, and how Lettsom came into possession of a turtle and instead of regarding it as a subject for comparative anatomy presented it to the society, together with an invitation to each member requesting the favour of his company at the King's Head Tavern in the Poultry on a June afternoon in 1775, where they made merry, feasting on its fat and its fins; and the house in Bolt-court which he gave for their meetings, and the many kind acts which he did—are they not written in the books of the chronicles of the eighteeth century? These books are of priceless value to this society, though they have not always been treated with becoming respect. But this Oration—to which you have listened with so much patient indulgence—will not have been in vain if it have the effect of obtaining for those old volumes appropriate bindings and a secure custody in a fire-proof safe. They contain the Log of our *Mayflower*, and they are well worthy, not only of our occasional study, but of our continuous and reverential care.

THE DISPERSION OF LUNATICS.—As illustrating the difficulty of finding asylum accommodation, the report of the West Sussex County Asylum Committee shows that 356 county patients are distributed as follows: Salisbury, 211; Haywards Heath, 1; Berry Wood, Northampton, 6; Portsmouth, 18; Camberwell House, London, 30; Grove Hall, London, 44; Hatton, Warwick, 36; Isle of Wight, 10.

The Ingleby Lectures

ON

THE OPERATIVE TREATMENT OF CANCER OF THE BREAST.

Delivered at Mason College, Birmingham, on May 19th and 26th,

BY BENNETT MAY, F.R.C.S. ENG.,

PROFESSOR OF SURGERY IN MASON COLLEGE, BIRMINGHAM.

LECTURE I.

GENTLEMEN,—When I accepted the invitation to give the Ingleby Lecture for this year I am afraid I did not sufficiently consider the difficulty I should find in selecting a suitable subject for the occasion, as the conditions of the Ingleby Trust and the objects of its generous founder necessarily limited me in my choice. It is true that all reasonable latitude is allowed by the council, to whom I have to express my sense of the honourable distinction conferred by their invitation. After some consideration I selected that of the Operative Treatment of Cancer of the Breast as being in a high degree germane to the benevolent purposes of the founder, as well as one on which I might claim to speak with some measure of observation and experience.

It may, however, be needful to say something in the way of an apology for its selection, as it has already been the subject of an Ingleby Lecture. The first of these lectures, given by Mr. Oliver Pemberton in 1884, was on the Treatment of Mammary Cancer. Since that period, however, much has happened in the surgical world; in particular, the great revolution in wound treatment, which set in about twenty years ago, has opened up quite a new and wider field for operative treatment. I believe I may say that practically it is only within the last fifteen years that any important advances have been made in our practice. It will be my chief purpose to review these advances and the results which have been obtained from them, and to endeavour to form an estimate of their value for future guidance. Mr. Pemberton's lecture was a very interesting and important one, and as he gave a very candid exposition of his experience it may be taken as representative of the best opinions of that date and of the surgical epoch over which his long and busy life extended. He quite endorsed the opinion prevailing among the profession, that no cases were less favourable for operation than these. The disease was regarded as practically incurable, and the most that was hoped for was a prolongation of the life and some amelioration of the sufferings of the patient. Most of us, indeed, remember the almost uniformly bad results; but for those whose memories do not go back so far reference to the surgical hand-books of the date is instructive and will serve as a basis of comparison with present-day results. Statistical tables *circâ* 1878–80 authorise me in stating that in about 50 per cent., or one-half, the cases operated on, local or regional recurrence—that is, external visible re-appearance of the disease—took place within three months, and in 85 per cent. within twelve months of operation; 90 per cent. of all cases were dead within two years, and the average addition to the life was variously estimated at from eight months to two years, but about thirteen months seems to have been considered the average. These results greatly influenced the theory of the disease and almost authorised the current and accepted views of the pathology of cancer and its incurability. But we now know that these views were, to a considerable extent at least, deduced from operations quite inadequate for the complete removal of the disease. The operation was a most inefficient one, only a small ellipse of the skin with the tumour and part of the breast being removed, and the axilla rarely emptied of its infected contents. This theory of cancer has been considerably modified by our more recent operations. I am not competent to discuss it, but I believe pathologists consider that, whatever may be the inherited or predisposing condition, cancer of the breast is primarily local and limited in its origin and not part of a general cancerous infiltration. Moreover, the channels of infection have been more carefully investigated, and we may follow the disease from its origin

Hosted by Google

into the various tissues is understood, and it is believed that a certain though varying interval intervenes before this local and general infection takes place.

I cannot discuss the parasitic theory of cancer, but so far I believe it is quite unproved. Possibly some micro-organisms may yet be discovered, and perhaps an antidote in the form of an antitoxin may follow; indeed, that prospect seems more hopeful than a purely therapeutic one; but at present the only lines on which we can successfully treat the disease at all are those of operation. As a result of the revolution in wound treatment, which I have referred to, the operative field has been greatly extended. We now ensure immediate union of the most extensive incisions, and operative mortality has been almost abolished. Consequently the operation has been continuously developed in thoroughness and completeness. The question is whether commensurate results have attended these wider operations, or are we pursuing a "will o' the wisp" which must continually elude our grasp? Further, what are the limits to which the operation may usefully be extended? The subject, it is to be hoped, will not now rest until some ultimate decision has been reached and a standard or minimum uniform operation has been settled upon. It probably can hardly be decided yet by appeals to statistics and percentages, as it will take several years to adjudicate upon the merits of different procedures. There is sufficient body of evidence, however, to leave little doubt upon the main point—viz., that there has been very substantial improvement in our results. Before going on to discuss this standard operation and the mode in which it should be carried out I will shortly indicate the steps of its development and the researches on which it is based. I think it was in 1867 that Mr. Moore, of the Middlesex Hospital, first enunciated the doctrine that the entire mamma, all adjacent structure, skin, fat, lymphatic glands, and more or less of the pectoral muscle must be extirpated. This view, however, was never acted upon, and seems to have been entirely lost sight of until Volkmann, in 1875, drew attention to the necessity of exploring the axilla in all cases, and soon after this Kuster advocated its systematic clearing out, whether the glands can be felt or not. Then Volkmann demonstrated how the pectoral fascia, whilst itself early becoming infected, acts as a barrier to the spreading growth of the carcinoma and seems for a time to bring it to a halt. His investigations were confirmed by Haidenhain, who observes that carcinomata invariably send their outposts to the surface of the muscle, no matter what the thickness of the fat may be. The muscle itself may remain healthy for some time. This is due to the fact that the direction of the lymphatic current is from muscle to fascia, and not in the inverse direction. But when the disease has extended into the muscle itself, which may be known by the tumour being adherent to subjacent parts and not moving in the direction of the fibres of the muscle when they are made tense, then the cells are swept along the lymphatic current by the action of the muscle, and the whole muscle must then be considered as involved.

That the lymphatics play the essential *rôle* in the dissemination and spread or the disease is established beyond controversy. They are the highways along which the cancer cells are conveyed. Stiles, in a valuable contribution to the anatomy and pathology of the breast in the Transactions of the Edinburgh Medical and Chirurgical Society, 1892, states that in cancerous breasts the lymphatics may frequently be seen injected with cancer cells. Recurrence or re-appearance of the disease after removal is due to the non-removal of microscopic foci or larger masses, more or less remote from the main tumour. Hence the importance of removing all the tissues which the lymphatics traverse as well as the glands themselves. The lymphatic vessels of the breast are described as being arranged in two layers. The superficial is close under the areola and round the nipple, and from this two or three trunks finally issue to pierce the deep fascia and join the deeper trunks. The deeper layer issues from the under surface of the gland and follows the fascia of the pectoralis major, receiving branches from that muscle. Hence the retro-mammary tissue and fascia are regarded as infected soil. The larger trunks accompany the bloodvessels of the gland, those from the inner, sternal periphery accompany perforating branches of the intercostals and join sternal glands within the chest. The greater number accompany the long thoracic, external mammary, and acromio-thoracic, to open into the axillary glands. Some from the upper periphery pass direct into other parts. The chronological order of the advance to the supra- and infra-clavicular glands above or beneath that bone. Stiles, however, states that the anastomosis and intersection of the lymphatics is so free that it is impossible to say to which set of glands the lymph from any given part of the breast may be conveyed. This statement, I believe, accords with clinical facts. We see the axillary glands infected with almost equal uniformity in whatever quadrant of the breast the growth is situated. Gross states that the seat of the primary disease exerts no influence on the date or frequency of the appearance of the lymphatic tumours in the axilla. Snow, however, finds that in cancer appearing close to the sternum the axilla is much more slowly infected than from other regions, and therefore considers this may be an exception to the routine practice of clearing the axilla. It is apparent that the supra-clavicular glands are more early infected in cancers of the upper periphery, and we may suppose that the sternal or mediastinal glands are early infected in those of the inner periphery. Hence the prognosis is, *cæteris paribus*, less favourable in these situations. The axillary glands, however, are commonly involved as well. The arrangement of the axillary glands is too well known to need description further than to add that they are probably much more numerous than the twelve or fourteen commonly given. The importance of the axilla as a resting place for the disease has always been recognised. It is the almost invariable seat of reappearance unless the glands are removed. It is believed that for a period the onward march is there arrested and the metastatic deposits delayed. It is doubtful whether general infection ever occurs without antecedent glandular infection. Gross says that it does in 3 per cent. of all cases running their course to a fatal end. This occurs only in the case of soft medullary tumours, the general infection taking place through the blood. It seems not unlikely that these may be cases of sarcoma. The region of gland infection may perhaps show wider latitude. Gross states that the axillary glands are infected in 90 per cent. of all cases running their course to a fatal end (without operation), and that in 7 per cent. glands other than the axillary—such as the mediastinal and suprascapular—become diseased without the axillary. But I do not think the axillary glands escape in 10 per cent., whatever others may be involved. I have never seen an advanced case without the axilla showing it.

The chronological stage at which the glands become infected is variously estimated and no doubt varies widely. Gross gives fifteen months after the inception of the disease as the average, but this is obviously fallacious, and six months is the more usual estimate of the time at which the glands can be felt by external palpation. As a matter of fact, it is very rare not to find them obviously diseased on opening the axilla at any stage at which patients come under operation. From the axilla the infection passes to the supra-clavicular glands in the posterior triangle of the neck. It is quite possible for these glands to become infected through more direct channels—viz., the lymphatics which pass above and beneath the clavicle. A long time may elapse before these glands show signs of enlargement on account of the loose fatty and areolar tissue among which they lie and the large space they occupy. The battle ground of controversy has now shifted from the axilla to this region, and there are numerous operators who attack the disease here as a routine procedure. The area of the breast has recently been shown to occupy a much larger extent than has commonly been supposed. Stiles in particular, by his nitric acid process, has demonstrated that the peripheral outlying processes extend far beyond the corpus. According to him the vertical diameter extends from the second rib to the lower border of the seventh costal cartilage or beyond; the horizontal from the edge of the sternum to the mid-axillary line. It sends peripheral processes into the retro-mammary tissue and fat, on to the pectoral fascia, so that no separation can there be made with the knife. To remove the whole breast it is necessary to keep outside the limits given. This must be done either by very wide skin incisions or dissecting the skin off the breast, to which it is closely attached by fibrous septa. Usually Stiles finds that the whole organ has not been removed by the surgeon's incisions, a fact which every surgeon must acknowledge. The significance and importance of this depends upon the part which may be played by the parenchyma of the breast, when not entirely removed, in the production of recurrence after operation. This is a question on which there is a good deal of diversity of opinion, but

Hosted by Google

nothing conclusive is known. Some have considered the whole gland as necessarily the subject of general cancerous infiltration, but I think this view is now generally abandoned. The German view, headed by Haidenhain, is that the whole parenchyma is liable to become cancerous from proliferative changes, and that there is a pre-cancerous condition the direct forerunner of cancer, into which it will sooner or later pass. The evidence in favour of this view, however, is rather hypothetical, and the gulf which separates them has not yet been bridged. The opinion of Creighton, supported by Jacobson, is that cancer in the breast is a disease due to the organ becoming obsolete, whereby the atrophying acini become so disordered as to allow the epithelium to escape and infect the surrounding connective tissue. Hence the connective tissue should be removed very widely beyond the breast. Others, with Stiles, contend that the special danger lies in the fact that the parenchyma of the breast and the surrounding tissues include the lymphatic spaces and highways along which the disease is liable to spread, and that it is impossible to say to what extent this has taken place in any case. Watson Cheyne also upholds the view that the special source of danger is the arrangement of the lymphatics and not the supposed pre-cancerous state of the breast. Butlin, again, does not consider that the new growth often arises in the outlying lobules, and therefore does not regard it as essential to remove the whole of the breast in every case when the tumour is small. What is certain is that occasionally on dissecting a breast after removal we find separate and independent nodules of which there was not the slightest indication beforehand. I have met with this twice, and its occasional, even if rare, occurrence is of itself sufficient to justify the removal of the whole breast in every case.

There is no positive evidence to uphold the view of the infectiveness of cancerous tissue itself if cut into. Indeed, if this were so we should expect to hear of the accidental inoculation of operators and others—a thing I believe absolutely unknown. This view, however, is strongly advocated by Halstead and Meyer in America and supported by Stiles, Watson Cheyne, and others here. It is believed that infection takes place either from direct inoculation by the knife or the liberation of cancer cells from their alveoli or the lymphatic vessels. The successful inoculation of cancerous tissue in animals has been accomplished and experimental grafting in man has also succeeded. Hence the importance of working outside the infected area and not cutting into infected tissues without adequate precaution. We should at least give the patient the benefit of the doubt by avoiding this.

Haidenhain and Volkmann about 1875 appear to have been the first to systematise a radical operation based on the preceding researches. The method of operating which they adopted has become classical and is the basis of our present procedures. It included the removal of the entire breast as believed, a liberal piece of skin, a clean dissection of the pectoral muscles, and in some cases removal of the axillary glands. This method of operating soon became universal in Germany, but it was much more slow to gain acceptance here. In 1880 Gross, of Philadelphia, and in 1883 Mitchell Banks here, did much to popularise by their writings thorough and extensive operations. Their operative mortality was high from septic diseases, which were then still rife, but their results were good. With aseptic wound treatment this high mortality has ceased and individual operators have been able to go on developing their operations in extent and thoroughness. The one which I adopt as the standard or minimum necessary to meet the conditions for cure I shall now proceed to describe. It includes the removal of the entire breast gland, the integuments over the area of the tumour and for some distance around, all the para-mammary fatty and areolar tissue extending upwards nearly to the clavicle, a clean dissection of the pectoralis major, or, what is better, the removal of the costo-sternal portion of the muscle, and, lastly, a clean dissection of the axilla, thus including all the tissues likely to contain the lymphatic channels. The suspected tissues are always to be removed entire in one piece, never cut into. This operation is frequently spoken of as the complete or classical operation, but as completeness in this matter appears to have no finality it is perhaps better spoken of as a wide or standard operation.

With regard to operation, the usual preparations for carrying out an aseptic operation are supposed, but no antiseptics or chemicals of any kind are to be introduced into the wound. I attach considerable importance to the proper planning of the incisions, which should be carefully outlined and marked on the surface. The incision usually conforms to the oval type or ellipse, a widely open oval, from four to eight inches wide at its widest part, according to the size and place of the tumour and the size of the breast; and ordinarily the long axis of the ellipse is in the direction of the pectoral fibres. The difficulty occurs in the case of outlying peripheral tumours, especially those lying near the sternum. In these some modification is necessary. The axis of the ellipse may be changed, but I now commonly adopt the suggestion, I think, of Bell—viz., to make a smaller second oval, including a triangular piece, the base of which joins the main ellipse at right angles, the result being a T-shaped incision. As a minimum distance two inches from the apparent margin of the tumour is advised, but I should take as much more as possible. The ellipse is to be carried out well over the axillary vessels. The incision extends down to the subcutaneous fat, and the integuments, with a sufficient layer of subcutaneous tissue but no more are retracted, so as to allow of a free dissection of the para-mammary tissue extending upwards nearly to the clavicle, inwards to the sternum, and outwards to the latissimus dorsi. The mass thus included is to be lifted up and thrown outwards, and in doing this one of two courses may be followed. Either the pectoral muscle must be scrupulously cleaned of every trace of its fascia and fat, or the costo-sternal portion of the muscle should be removed with the breast, &c. I think the latter is far the best way and should usually be done. The inner or sternal attachment is severed, and the separation may be made by the finger or handle of the scalpel working in the interval between the two parts of the muscle, and finally the outer attachment is divided near the humerus. This is really easier and quicker than an elaborate dissection of the fascia, which is nearly sure to be imperfect. It has the further advantage of a more thorough exposure of the axilla, especially the dangerous region between the two pectorals, and it also allows more easy approximation of the flaps of skin in case they are deficient, and thus permits of wider removal of the integuments. Of course, if the tumour is adherent to the muscle, this much is necessary as a minimum. As the dissection proceeds the breast with surrounding tissues, &c., is cleared from the chest wall and thrown outwards towards the axilla. The vessels, which have been taken up with catch forceps, may now be tied off and the dissection of the axilla proceeded with. In doing this it is well to expose the axillary vein where it is superficial at the outer angle early in the procedure. The fascia over it is to be divided, and the vein can then be safeguarded by the finger used as a director while the fascia is further laid open. For the most part the dissection is to be made clean with the knife, but the vein may be quite sufficiently and more safely cleared with flat, blunt-pointed scissors and the finger, unless it is positively adherent to the growth. All large vessels, such as the subscapular vein, should be clamped before division and tied at once. It is usually a fairly easy matter to follow and detach the axillary contents quite up to the apex and reach the clavicle, the pectoral muscles being relaxed and strongly retracted for the purpose. If any difficulty is encountered in doing this the great pectoral muscle should be cut across and the ends thrown apart. The muscle can be afterwards fully restored by buried catgut stitches. This is especially indicated where there are fulness and large veins in the pectoral and infra-scapular region, as if the muscles were lifted up by glands beneath them. Many contend that it is not possible to clean the axilla without division of both muscles or even their complete removal. If an absolute cleaning of the space and subclavicular region is implied this is correct. It cannot be done without dividing the muscles, but under ordinary favourable conditions, when the glands are small and non-adherent, simple cleaning in the way indicated is quite sufficient. We never find the disease reappear in the axilla in these circumstances. As a matter of fact, it is remarkable how efficient the clearing of the axilla is in preventing recurrence in this situation. If the glands are large and adherent the dissection is more difficult and must be more thorough. Muscles may be freely sacrificed, and if the tumour is adherent to the vein it must be very carefully dissected off its coats. In a few cases the vessel will be inseparable from, or will be flattened out and entangled in, the growth, so that no separation can be made with the knife. In these circumstances any necessary length of the vein may be removed between two ligatures, as I have done on two occasions. There is not, however, any hope of a permanent

Hosted by Google

cure if it has advanced as far as this, still less if it involves the large trunks of the brachial plexus.

Having cleared the vessels, we may next proceed to detach the axillary contents from the lateral wall of the chest by quickly stripping up the thin fascia which attaches them to the serratus magnus and the ribs, avoiding injury to that muscle's nerve in doing so. The posterior wall is then to be cleaned, and this is frequently the most troublesome part of the procedure, on account of the hæmorrhage from the subscapular vessels. These should be exposed and caught before they are divided. The nerves, however, may nearly always be spared uninjured. The cutaneous nerves which cross the axilla may be sacrificed without much inconvenience. The whole mass, including the breast, contents of the axilla, and other intervening tissue, is to be removed entire by working outside it, so that it is not cut into. The external wound may be most quickly and easily closed by a continuous stitch of fine wire. If there is great tension I think the ordinary interrupted stitches serve best, starting from the angles towards the centre. They should be inserted near the edges and close together, about three or four to the inch, so as to distribute the tension equally. It is surprising how large a gap may safely be approximated in this way if the flaps have been well separated by the dissection. I have given up all kinds of button or deep stitches. I have not been able to give up the drainage-tube entirely. I drain the axilla by a tube perforating the posterior flap to carry away the blood and lymph, which are sometimes rather abundant and which may otherwise distend the flaps.

The proper putting up of a breast is important and not easy. Firm, smooth compression is required over a voluminous dressing. I use nothing but dry absorbent wool with a protection of gauze over the incision. As a rule two dressings suffice—one in forty-eight hours to remove the tube, and the other on the ninth or tenth day to remove the stitches. The axillary portion invariably heals by the first intention, and the remainder also if care be taken in the putting up. Objections to this operation have been taken in the stiffness, œdema, numbness, and neuralgic pains which are said to follow it. In my experience inconvenience from these is not considerable and need not weigh in the slightest degree against the operation. Any œdema will be due to over-pressure in the axilla and soon passes away. Passive movements of the shoulder and elbow should be begun early and the movements of the arm become nearly perfect again with time and use.

The mortality from this operation is remarkably low. I do not think it should ever exceed 2 per cent. from causes proper to the operation. I have not had a death in seventy-six consecutive cases, but one of my patients died from intestinal obstruction three weeks after operation. The old high death-rate was almost wholly due to septic diseases. I think shock is the principal danger to be feared, but by preventing loss of blood and unnecessary exposure to cold this is rarely formidable. The operation should be done as quickly as is consistent with thoroughness, and facility in doing it is to be acquired by practice. Occasionally some intercurrent disorder, such as bronchitis, may carry off a patient, but in every case the patient's fitness to bear the procedure must be considered on general surgical principles. There are a few other points to be noted. In planning the incisions regard must be had primarily for the efficient removal of the growth without reference to the subsequent approximation of the skin. But if the case is suitable for operation this can generally be accomplished. A small gap may be relied on to fill up quickly without suppuration if the wound be kept dry and aseptic. I have had some success in primary skin grafting, but it is uncertain. I have on occasions used a piece of the redundant skin which is cut away near the axilla. It is to be stripped of all fat and tissue and kept in warm boracic lotion till wanted. It may then be shaped to the gap, which it should nearly fill, and should be pressed down firmly so as to maintain close apposition of the raw surfaces. It is more certain of success, however, if the large piece is cut into small portions about a quarter of an inch square and planted near the edges. Operative grafting after eight or ten days is the most successful, a strip being taken from the inner side of the arm or thigh, but on many grounds it is objectionable. It is useless to operate in cases of wide skin infiltration or with scattered tubercles, as the most extensive sacrifice of skin cannot cure these. Regionary recurrence in the skin and internal metastasis are to be expected.

If we find during an operation that the highest axillary gland is involved so that it is not possible to pass beyond the limits of the disease, what are we to do? I have no doubt, under these circumstances, the posterior triangle of the neck should be opened and cleared of its glands as an addition to the ordinary operation. There is a reasonable chance of getting beyond the limits of the disease. The incision may be prolonged upwards over the clavicle, but it is not necessary to divide or resect that bone, as has been done by some operators. I have on two occasions cleared the supra-clavicular fossa of its glands in this way, though, as they were rather advanced cases, the results were not very satisfactory, and the disease returned *in osco*.

CASE OF SOLID FIBROID TUMOUR OF THE OVARY.

BY C. E. PURSLOW, M.D., M.R.C.P. LOND.,

HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM; ASSISTANT TO THE PROFESSORS OF MIDWIFERY AND GYNÆCOLOGY, MASON COLLEGE, BIRMINGHAM.

AN unmarried woman, aged twenty-six years, was admitted to the Queen's Hospital, Birmingham, on Dec. 10th, 1895, complaining of swelling of the abdomen. She had felt some pain and discomfort on the right side of the abdomen for five months, but the enlargement had been noticed only a few days previously. Menstruation had been regular, but for the last six months the amount had been less than previously. She had had pain on defecation for four months, and for some weeks before admission had complained of frequent desire to micturate. On examination the abdomen was found to be considerably distended. A hard, nodular, irregular tumour could be felt in the lower part of the abdomen reaching up to the umbilicus. The tumour moved freely under the hand and appeared to float in some fluid, and gave a sensation of "ballottement" when pressure was made with one hand, the other hand being applied to the opposite side of the abdomen. The physical sign obtained in this way resembled in a very marked degree that due to a fœtus in utero. Bimanual examination, however, at once made it clear that the tumour was independent of the uterus. Percussion proved that the fluid in which the tumour floated was free in the peritoneal cavity. On Dec. 16th the abdomen was opened in the middle line. The incision was extended up to the umbilicus. About three pints of free ascitic fluid escaped. The tumour was then manipulated through the wound, and the pedicle, which proved to be a long one, was transfixed and tied with silk. The parietal peritoneum was seen to be injected, and its cut edge bled freely, but no adhesions had formed. The tumour grew from the right ovary and the left ovary was normal. No washing out or drainage was used, and the wound was closed by silkworm gut sutures. The wound healed by first intention. The patient made an uninterrupted recovery and left the hospital on the twenty-fourth day after the operation. The tumour, which was irregular and nodular in shape, weighed forty-one ounces; it was solid throughout. Sections of it were kindly examined under the microscope by Dr. Kauffman, pathologist to the hospital, and he reported that it was composed entirely of fibroid tissue, which in some places was undergoing fatty degeneration.

All writers on gynæcology agree in stating that solid non-malignant tumours of the ovary are rare, and in most of the text-books the subject is dismissed in a few lines. A full account of them is given in Pozzi's work on Gynæcology, and he mentions one or two characteristics which were present also in this case; he states that they are almost invariably associated with the presence of free ascitic fluid and as a rule are free from adhesions. The Fallopian tube is usually quite free and is not adherent to the surface of the tumour, as is the case with cysts of the ovary; that is well seen in this specimen. He also states that they most often occur in comparatively young women. The presence of free ascitic fluid excites the suspicion of cancer, but in this case the fact that there was little pain and no loss of flesh was against that idea. For many of the notes and for valuable assistance in the treatment of the case I am indebted to Mr. F. G. Messiter, obstetric house surgeon.

THE REPRESENTATION OF THE FUNCTION OF VISION IN THE CEREBRAL CORTEX OF MAN.[1]

BY SEYMOUR J. SHARKEY, M.D. OXON., F.R.C.P. LOND.

ON May 8th, 1883, I read a paper before the Royal Medical and Chirurgical Society on "A Case of Asymmetry of the Brain presenting peculiarities which bear upon the Question of the Connexion between the Optic Nerves and certain Definite Areæ of the Cerebral Cortex."[2] The case was one of congenital spastic hemiplegia, and the most striking peculiarities of the malformed half of the brain were as follows:—(1) The general arrest of development of the left hemisphere; (2) the small size of the corresponding crus cerebri and anterior pyramid; (3) the absence of the angular gyrus and superior temporo-sphenoidal convolution, together with fusion of some of the other convolutions of the left temporo-sphenoidal lobe; and (4) the small size of the optic tract, optic thalamus, and corpora geniculata on the same side. I might have added, I now think, that the angular gyrus in the healthy hemisphere appeared to be unusually large. In commenting on this case I wrote as follows: "Some physiologists have concluded from their experiments that the occipital lobe contains visual centres, and of late Ferrier himself has inclined to this view. The present specimen tells neither for nor against such a theory, for the slight reduction in the size of this lobe cannot be made responsible for the extreme atrophy of the optic tract, though it is possible that the remnant of the latter which still exists may owe its survival to the presence of the occipital lobe. The case is different, however, with the angular gyrus and temporo-sphenoidal lobe. Ferrier's experiments have raised a very strong presumption in favour of the theory that the angular gyrus has some special function in relation with sight, some intimate connexion with the optic tract. And we hold that the specimen under consideration affords anatomical confirmation of this view. Setting aside the central convolutions and the degenerate motor strands in relation with them, the rest of the left hemisphere, with the striking exception already mentioned, presents only such general slight diminution in size as will explain any inequality which may exist between the nerves proceeding from the two sides. But the angular gyrus and temporo-sphenoidal lobe on the one hand, and the optic tract, optic thalamus, and corpora geniculata on the other, are so exceptionally malformed and deficient that some interdependence between them is at once suggested. And although from a consideration of this single anatomical specimen we are not justified in making any more precise assertion, still, we can scarcely avoid looking upon it as confirmative of those physiological experiments which point to the angular gyrus as in some way bound up with the function of vision."

On June 10th, 1884, I read another paper before the Royal Medical and Chirurgical Society on "Embolism of the Right Middle Cerebral Artery producing Left Hemiplegia and Hemianæsthesia; Absorption of a Large Portion of the Right Hemisphere; Death Seven Years Later."[3] In this case the patient had been suddenly attacked, seven years before her death, with embolism of the right middle cerebral artery, which resulted finally in the destruction of a large part of the right hemisphere. At the time of her attack she was in Guy's Hospital, where careful notes were taken. From these it appeared that after being unconscious for four days she was found to have, in addition to left hemiplegia and hemianæsthesia, dimness of vision in the left eye almost amounting to complete blindness, though the patient said that she saw perfectly before the attack. Hearing was good in the right ear, but almost absent in the left. Six and a half weeks after the commencement of her illness sight and hearing were completely restored. Seven years after this attack I performed a post-mortem examination on this patient and found that the following convolutions had been destroyed on the right side: the inferior frontal, the external portion of the orbital, the lower half of the two central convolutions, the inferior parietal lobule, the convolutions of the island of Reil, the angular gyrus, the superior and middle temporo-sphenoidal, and part of the inferior occipito-temporal convolutions. The conclusions I drew from this case are as follows:—1. That if the angular gyrus and superior temporo-sphenoidal convolutions be respectively connected with sight and hearing on the opposite side of the body their destruction does not involve permanent loss of these special senses. Such an inference agrees with the results of experimental removal of the angular gyrus, an operation which has been found to produce crossed amblyopia, from which the animal soon recovers. 2. That each hemisphere is specially connected with the sight of the opposite eye. In a recent paper by Dr. Allen Starr on the Visual Area in the Brain the writer adopts the statement of Mauthner, made in 1881, that "there is no case well authenticated in which lesion of one hemisphere has produced blindness in the opposite eye"; and he concludes that "when a lesion of one hemisphere involves the optic fibres at any point partial blindness of both eyes, and not blindness of the opposite eye, is produced." Although I have seen cases where hemiplegia with hemianæsthesia, including loss of sight and other special senses, occurred on the same side of the body, and where a lesion of the opposite hemisphere appeared to be the cause of all, I have never before had the opportunity of verifying the fact at a post-mortem examination. As very careful notes of this case were made at Guy's, Hospital and on examination the left eye was found to be amblyopic and the right not, the conclusion that each hemisphere has a more special connexion with the opposite retina than with that on the same side seems to me to be legitimate.

During the early part of last year Dr. Wainwright, senior resident medical officer of the Evelina Hospital, brought a brain to Mr. Shattock, and the latter very kindly handed it over to me to make what I could of it. I saw at once that the specimen might prove to be of great interest, and I accordingly examined it carefully after due preparation. I found that there were bilateral softening and atrophy of a very marked kind involving the brain in the region of the Sylvian fissure symmetrically, but in unequal degrees on the two sides. The area involved was most entensive in the left hemisphere (Fig. 1). The ascending frontal and ascending parietal convolutions, the inferior parietal lobule, the angular gyrus, and the greater part of the temporo-sphenoidal lobe were practically gone, being atrophied and shrunken to the last degree, and presenting the rich brown tints so often present in cerebral softening. On the right side (Fig. 2) the ascending frontal and the greater part of the ascending parietal convolutions were intact, as were the two annectant convolutions forming the superior parietal lobule. The inferior parietal lobule, the angular gyrus, the superior temporo-sphenoidal, and the neighbouring parts of the middle temporo-sphenoidal convolutions were much atrophied, discoloured, and degenerate. The left crus cerebri was much smaller than the right. On both right and left side the occipital lobe was quite intact. The central ganglia on the left side were atrophied and much smaller than those on the right, which appeared to be normal. The softening in the left hemisphere was evidently extensive both in superficial area and in depth, while that on the right appeared to be very superficial and confined to the cortex. On both sides the occipital lobes were quite natural in appearance. In order to see whether the fibres which pass from the occipital lobe to the internal capsule were diseased or intact a horizontal section was made which passed through the middle of the softened area and into the central ganglia, displaying the whole course of fibres in question (Fig. 3). This was done on both sides of the brain and very successfully brought to view the radiating fibres of the occipital lobe and the long bundle formed by them on their way to the internal capsule. The softening in the right hemisphere proved to be quite superficial; it had not reached or altered in the least degree the occipital fibres. In the left hemisphere these fibres appeared also to be quite healthy; only at one spot in the section did the orange yellow colour of the softening reach them, and even there the fibres appeared to pass along without any alteration. Mr. Shattock, who made the sections in my presence, confirmed these observations. The result of the examination therefore amounted to this, that in the left hemisphere there was a wide area of destruction affecting the parietal lobe and the angular and temporo-sphenoidal convolutions; in the right there were softening and shrinking of the inferior parietal lobule and of the angular and temporo-sphenoidal convolutions only, while

on both sides the occipital lobe was intact. The symmetrical lesion in this child's brain suggested that it might have originated in instrumental delivery. The atrophied convolutions included these which have been bilaterally removed in animals for the purpose of investigating the localisation of sight and hearing in the hemispheres. Just such an experiment as this by disease is what has long been wanted, and on seeing this specimen great hopes were awakened in me as to its probable value. I wrote therefore to Dr. Wainwright and asked him to be kind enough to send me the child's history. He replied that the child was two and a half years of age and had been quite well until six years old, when he had a fit and lost power in the right arm and leg. After that these limbs gradually got rigid. The general health, however, was pretty good until fourteen days before admission, when cough and wasting set in. Advanced tuberculous disease of the lungs was then found, and the child was miserably wasted. The right arm and leg were contracted, and the contraction could only be overcome with difficulty and with the production of much pain. The right knee-jerk was absent; the left was active. The fundi of the eyes were healthy; there was neither optic neuritis nor atrophy. The child appeared to be stone deaf. He died gradually after some weeks. His birth had been perfectly easy and natural and no instruments were used. As I wanted to get the facts as regards deafness I wrote again to Dr. Wainwright and also inquired as to vision. He replied: "As regards deafness, I found it impossible to rouse the child by any amount of noise; it would not even look round, though it answered quickly to touch. The nurses also failed entirely to find any evidence of hearing. At one time it was put in a bed with another child who was screaming in a most frantic manner; though quite awake it did not even turn towards it. The child was always considered to be quite blind, but it had some sensation to light in the left eye, I think, as it used to get worried if one focussed light on it for some time." I wrote again to Dr. Wainwright asking him to give me the facts which convinced him that the child was blind. He replied: "I spent a good deal of time on several occasions examining the child's eyes for optic changes and tubercles and it never took the least notice of the light, never showing the least tendency to object or even to blink except in the case of the left eye, which sometimes after a while seemed to be irritated, and it would rub it. It was very

keen about its food, but unless its lips were touched it made no effort to get at it when a spoonful of anything was offered it. As circumstantial evidence, I may mention that the nurses say they always thought that everyone acknowledged that it was blind. As to your question about mental dulness and apathy, I may say it was not exactly lively, but it was quite sensible, and it never until quite the end showed any sign of coma, and it was in the hospital sixty days" The evidence as to blindness and deafness being satisfactory, I wrote again to Dr. Wainwright asking him to question the parents as to whether the child had ever seen and heard. Great difficulty was experienced in finding their whereabouts, as they had moved, and when they were at last traced they evinced considerable annoyance, as they had done before, at being bothered about the child, as they could not understand what good reason we could have for the trouble we were taking. However, both mother and father asserted that they were quite positive that the child used to see and hear well. Such are the anatomical and physiological facts which I have to record in this case. What gave rise to the superficial atrophy and softening of the right inferior parietal lobule and angulo-temporal convolutions I cannot say. If we disregard the hemiplegia on the right side of the body which was produced by the disease of the convolutions of the parietal lobe on the left, we have remaining a bilateral destruction of the inferior parietal lobule and angular and temporo-sphenoidal convolutions on both sides, while the occipital lobe and its radiations are intact. As far as one can see, that is so on both sides; even if this be doubtful in the left hemisphere it seems free from doubt as far as the right is concerned. Granting, then, that the original lesion in the left hemisphere which gave rise to the hemiplegia may have produced temporary blindness and deafness in the opposite side, which soon recovered, the facts of the case seem to indicate that when the inferior parietal lobule and angulo-temporal convolutions of the right hemisphere also became diseased the patient's sight and hearing were abolished.

The three cases which I have brought forward supply important evidence, each in its own way, of the relation of the region of the angular gyrus to vision. The first or anatomical specimen, though very suggestive, is lacking on the physiological side. In the other two cases we have both the anatomical appearances and the physiological changes which accompanied them, and I think they deserve the title of striking cases. But they have the defects which almost all such cases must have; anatomically it is difficult to state the precise limitations of disease; and physiologically we would like to have some further details. But it must, I fear, generally be so with our observations on man. In experiments on animals, however, even if the difficulties of correctly estimating physiological changes be surmounted, which are more than ordinarily great in experiments relating to the functions of the brain, and if the exact limit of the injuries inflicted can be determined there still remains the fact that the knowledge gained of cerebral physiology in animals cannot be directly transferred to man. It serves as a beacon to guide our observations at the bedside and in the post-mortem room, but it still lacks that confirmation which alone can justify us in accepting it as a part of human physiology. Therefore, defective as the three cases may be, they appear to be worthy of forming links in the chain of evidence which finally leads to the solution of such questions. I suppose most clinical observers will admit, as I do, that the occipital lobes are very intimately connected with vision, and are, in fact, "half vision" centres. But it would be interesting to know whether the members of the society are inclined to limit the visual area in them to their internal or central aspect. To me it seems that the facts of disease do not warrant such a conclusion, but that hemianopsia results from destruction of the cortex on the external aspect as well. Hemianopsia is so persistent when once developed that it must be allowed that one occipital lobe cannot make amends for disease in the other, whereas one angular convolution can speedily enough make up for the temporary blindness produced by destruction of the other. How is it, then, that although each angular region seems to be able to subserve vision in both eyes it cannot make up for hemianopic defect produced by disease of the occipital lobe? The only explanation I can see is that the occipital lobe is a lower centre through which visual impulses must pass on their way to the higher centres in the region of the angular gyrus, and that disease of the lower centre or of the fibres in connexion with it intercepts the visual impulses on their way to the higher centres. But each higher centre being connected with the whole of both occipital lower centres, destruction of one does not interfere permanently with vision in either eye. Considering the important part which is played by mental vision in the higher intellectual processes in man it is not to be wondered at if he is found to possess high visual centres in an advanced state of development, although such centres may be non-existent or only rudimentary in animals below him in the scale of existence; indeed, clinical experience seems to show that mental blindness, and especially that variety of it which is called "verbal blindness," is associated with disease of the inferior parietal lobule which lies in front of the termination of the fissure of Sylvius. This convolution is continuous above and behind with the angular gyrus. The conclusion to which my cases seem to point is that the convolutions surrounding the posterior extremity of the fissure of Sylvius are specially concerned with the vision of the opposite eye, and in such a direct manner that destruction of them in one hemisphere produces transitory blindness of the opposite eye, while bilateral destruction of them causes permanent blindness in both eyes.

Harley-street, W.

ON VARIOUS FORMS OF TALIPES AS DEPICTED BY X RAYS.

BY RICHARD BARWELL, F.R.C.S. ENG.,
CONSULTING SURGEON TO CHARING-CROSS HOSPITAL.

(Concluded from page 909.)

AT first, and while those changes in the position of bones depicted in my last paper are still recent, acquired valgus and flat foot may be temporarily re-dressed by comparatively slight pressure with the hands. Herein it differs from the congenital form, which is stiff and unyielding from the very first.[1] The post-natal acquisition of valgus was traced in my last paper, and was shown to be due to insufficient, rather than to exaggerated, action of certain muscles, especially and primarily to weakness or sluggishness of the flexor longus hallucis permitting the os calcis to roll over on to its inner side, thus allowing the sustentaculum tali to droop and causing the head of the astragalus to fall into the sole. Such fall of necessity entails abduction on each other of the two halves, anterior and posterior, of the tarsus. When this false position has lasted a certain time the fasciæ and ligaments on the inner side of the foot become loose and thin, the tibial muscles weak and lengthened, while the fibrous structures on the outer side as also the peronei contract and adapt themselves to the acquired shortness. Thus after a certain period the foot is so firmly fixed in malposture that it cannot without certain adjuvants be rectified or much improved in shape by the use of any moderate manual force, thus in that matter of fixity simulating very much more the congenital type of the deformity. We have then, in formulating methods of treatment to deal with very different degrees of the evil, the slightest of which requires very little more than certain modifications of the foot-gear and better regulation of walking. Hence, though some of the details here mentioned may seem mere trivialities, they are not really so; their intelligent and persevering use will cure a large proportion of all but the more severe class of cases. Many young people, more commonly girls, are brought to me with lengthened feet almost devoid of instep, with straight or concave outer border, the internal malleolus almost effaced, and the head of the astragalus quite visible and projecting (see Fig. 13[2]). Such patients in walking turn the feet too much out, and a large proportion of them have the great toe forced outwards, the second toe either lying upon it or less commonly beneath it. This posture of the big toe may be, indeed is, very frequently the starting point and cause of the whole trouble,

[1] It has been already pointed out that congenital valgus is always, or very nearly always, combined with calcaneus, or less commonly with equinus. These conditions are not our subject just now (see THE LANCET, Jan. 30th, 1897). In future the one word "valgus" will be used to include also flat foot.

[2] THE LANCET, Jan. 30th, 1897.

for it cannot do its proper work of propelling the body forward when the foot is behind and just previously to being lifted from the ground. This work that ought to be, but cannot be, done by the second phalanx of the hallux, thus misplaced, is taken up by the head of the first metatarsal bone. Such deleterious position is generally the result of bad foot-gear coming to a point in the mid-line and frequently too short. Another error is generally overlooked, because the shoe measures as long or even a little longer than the foot, but looked at from the side may be seen to have the front part of the upper leather so closely sewn to the sole that there is no room for the toe, which having to find space further back is pressed outward into the same position as though the shoe were actually short. The result of this improper shape is frequently still further aggravated by high narrow heels, which not only cause the foot to slide forward into the already overcrowded toe of the boot, but by increasing the height of the foot from the ground and decreasing the size of the supporting surface greatly aggravate the tendency to turn over on the inner side. It is very difficult for surgical advice to contend against the tyrannies of fashion; but, if the patient can be induced to adopt common sense as a guide, much way towards cure will have been made. Nevertheless, he must usually go further and cause the foot-gear to be not merely harmless, but actually remedial by throwing the foot somewhat over on to the outer margin. A wedge of leather fastened with brads under the inner margin of the heel and one of a semicircular shape under the ball of the great toe will effect this object. According to the severity of the case these should be at the thickest part a little under $\frac{1}{4}$ in. or $\frac{3}{8}$ in. in thickness at the margin in the one locality and at what would be the centre of the circle if completed in the other. By this means station and progression, instead of augmenting the faulty posture, tend to reduce it. I must, in this connexion, strongly animadvert upon those unsurgical contrivances called "valgus pads" and "surgical soles," that is to say, lumps of slightly varying shapes placed inside the boot so as to press on the inner side of the sole. Now, one important factor, part of nature's mechanism, for keeping up the arch is the tie-beams stretched from one to the other buttress—namely, the plantar fascia and the abductor pollucis. Pressure upon them by those pads and lumps must, and does, cause their atrophy and relaxation, and then by pressing on the internal plantar nerve leads to paresis of all the muscles of the sole thereby supplied. There is the more reason for condemning these inside lumps since the outside wedges above described, by turning the foot sufficiently, secure all the advantages without the injurious effects of those contrivances.

To return to the position of the great toe. When this is abducted only to a moderate degree it will generally, when clothed in properly made foot-gear, regain its proper posture; but a greater degree of distortion requires some extraneous aid, and in all but the severest forms a toe-stall of some thin material, butter-cloth for instance, can very easily be cut to fit and stitched. It must have a tongue or lappel at the inner side to which a loop of flat elastic is sewn, which, hitched under and behind the heel, makes quite sufficient traction to rectify the malposture. The "toe-post," a piece of thin metal projecting from the sole of the boot between the first and second toe, is very often painful; it acts with too rigid coercion, and if the hallux be much abducted it is generally impossible to introduce it on the proper side of the post unless the shoe laces quite down to the toes. But by one or other of the above methods, or, as some like to do it, by means of strapping plaster, the toe must be restored to the proper line. In the meantime, and more especially after this has been effected, exercises such as are fitted to strengthen the long flexor of the toe and also the tibial muscles, are to be sedulously employed. Space forbids a full description of more than a few of these. One of the most important is to make the patient walk on the outer margins of nude or merely stocking-clothed feet, or, if they be too feeble to allow of locomotion in that posture, then to lift them and let them fall into the usual plantar attitude alternately. In sitting, too, they should be so kept as a more or less constant habit, and frequently exercised by placing them fairly on the floor and turning them on the outside in pretty rapid alternation for some minutes at a time. These exercises are directed to the two tibial muscles, and Faradaisation of them is often desirable. The most important object, however, is to restore activity and power to the flexor longus hallucis; the digit should be restored, even if only temporarily by the toe-stall (*vide supra*) or by plaster. The patient, if the part has been long thrown out of gear, must first learn again to use the muscle by so placing the sole on a book or block of wood that the toes project beyond the edge, and then must continue to bend the last phalanx at rapid intervals over that edge till fatigue comes on. A nut or hook can be fastened to the corner of the block, and an elastic band so attached and hitched over the toe as to draw it into position while it is being thus exercised. When sufficient power has been regained, or *ab initio* in slighter cases, the patient should two or three times a day exercise the part by rising on the toes first of both feet then of only one foot; but some watchfulness is required to see that the great toe is really used, and not merely the head of the metatarsal bone. These exercises may of course be varied in manifold ways; by their judicious use many cases of nascent and of older but not very severe valgus may be cured. But when the deformity is further advanced, when the foot is quite rigid, so that little or no change of form can be produced by manual pressure without additional aid, the condition requires more cogent treatment. As a general rule tenotomy is unnecessary and undesirable. 1. Unless valgus be combined with equinus, when such addition is pretty well marked division of the Achilles' tendon is desirable, as saving much time, as also discomfort and pain. 2. When considerable abduction of the anterior on the posterior tarsus cannot be completely rectified by the surgeon's hand, even though methods of annulling muscular contraction are employed, section of the peroneus brevis tendon is under such circumstances desirable. The best place for this is a little behind the base of the fifth metatarsal bone, which makes an easily found prominence. The tendon lies rather on the upper margin of the rounded outer border of the foot; the tenotome should be introduced superficially and the division take place towards and down to the cuboid. Only in quite exceptional cases is the peroneus longus to be divided; if done at all the proper point of section is on the os calcis, in front of the peroneal tubercle. When both tendons are to be severed (in very exceptional cases only) the selected point should be below and in front of the malleolus. On no account should section be made behind the fibula. The tendons overlie each other, hence impossibility of securing division of either separately; they are also very closely packed, therefore in healing they always adhere together, and nearly always also to the fibrous sheath, thus confusing, embarassing, or entirely annulling their action.

One of my reasons for deprecating section of tendons in most cases of valgus is the fact that by eliminating muscular and ligamentous resistance, by means that will be described immediately, the foot can, as a general rule, be brought into good position, in which it must be retained by plaster-of-Paris. The mode of procedure is thus: the extremity having been rendered passive, the surgeon, holding the anterior tarsus in one hand and the posterior in the other, overcomes the abduction of those parts; if there be much difficulty in this he will find assistance by placing a loop of bandage on the inner side of the mid-tarsus where the head of the astragalus projects; the ends of this passing over the instep and under the sole respectively are confided to an assistant holding them firmly on the outer side of the foot, making thus counter-extension. After overcoming abduction, the rotation is to be corrected. I find it best to achieve this by first plantar flexing the tarsus with some little force, and then turning the foot, more especially the anterior half, so that the sole looks somewhat inward. While the extremity is in this posture, a cotton-wool bandage is to be applied.[3] It often is desirable to supply a heel for the patient to walk on more comfortably. Pieces of rather stout, fine felt, previously cut to the shape required, are to be placed below the natural heel until the requisite thickness is attained—i.e., until the last piece lies on a level rather lower than the rest of the foot; they can be retained in place by the wool roller while the plaster bandage is being adapted. The bandages must be put on from without inward—i.e., the start being made from the outer margin of the foot, the bandage passes from that border under the sole to the inner border; this choice of direction for bandaging is by no means a trivial matter. When the plaster bandage is properly in place the position of the great toe must be attended to; the valgous condition

[3] Several of these should be at hand; they are easily made by unwinding a fresh sheet of the wool, and cutting the strip of proper width with long-bladed sharp scissors.

Hosted by Google

being corrected with the hand, the centre position of a narrow piece of bandage is to make one, or at most two, turns round the ungual phalanx; the further edge, somewhat projecting, must be gathered together by a few stitches; the ends of the bandage are then brought down along the inner margin of the foot, and there secured either by a few more turns of the plaster bandage or with wet, loose plaster, care being taken to hold the toe in good position and with the other hand to keep the ends of the bandage, which for the present project behind the foot, tight. During the application of the bandage the surgeon must continually verify the posture, taking care that the three faults are all corrected; there must be a good arch, the outer border must be convex, and there must be such considerable inward rotation that the outer border of the sole lies on a level considerably lower than the inner. There is no occasion whatever for making that border of the appliance thick and heavy with additional plaster. If the plaster bandage be properly applied the foot cannot turn; it is impossible for the patient to stand otherwise than on the outer border of the sole; the felt used for making a heel is far lighter and more elastic than a heavy lump made in that situation with plaster. The appliance should be worn for about a month, during which the patient is to walk about and, above all, to sedulously practise bending the last phalanx of the great toe, the bandage on which may have to be renewed two or three times during the specified period. It is rare that the plaster-of-Paris bandage requires renewal; the foot is by that time cured of deformity, but is weak. The wedge-shaped soles as above described must be used; the shoes must have broad, flat heels; and the exercises already specified should be persevered with. In some of the severer cases a poroplastic splint, easily removed and replaced, should be moulded to the foot, rather strongly rotated inwards, and used only during the night.

A few words must be said about the means of procuring passivity of the foot while it is being forced into good position and bandaged. The influence of nitrous oxide gas is too evanescent; even if the appliance could be completed the plaster would not harden while anæsthesia lasted, and if the patient struggled during recovery—a very probable event—it would crack. Ether, of course, gives ample time and opportunity, but it is well when possible to avoid the risk, the subsequent sickness, and the discomfort. Keeping the foot for thirty or forty minutes in hot, dry air has the effect of rendering the ligaments and muscles singularly limp and flaccid. The method is not altogether new, though my arrangements are so, and I carry out the object thus. A square box, properly made of semi-steel and of commensurate size, and having the metal well protected by thick felt, is placed on a tripod over a Fletcher gas-burner; within it a sling of four-inch webbing permits the patient's foot and about half the leg to rest at ease; a thermometer ranging up to 350° F. is secured, so that the temperature is easily verifiable. The patient is seated; he places his foot in the box at a temperature of about 80°; the thermometer slowly rises, the limb sweats, the air soon becomes much charged with moisture, and the heat would very soon become unbearable, for damp air cannot be tolerated when heated. Therefore the patient is warned that as soon as the heat causes the least unpleasantness he is to mention the fact. The air is then pretty rapidly but gradually changed by means of a powerful pneumatic pump. This change affects but slightly the temperature, which can thus be kept up to between 250° and 300° for, as I have said, from thirty to forty minutes, at the end of which time—very rarely is a longer time required—the foot is quite flaccid and may be twisted or kneaded into good form, and the cure completed by the plaster bandage, followed by exercise as above described.

Wimpole-street, W.

A METHOD OF UNITING THE DIVIDED INTESTINE.

BY G. LENTHAL CHEATLE, F.R.C.S. ENG.,
ASSISTANT SURGEON TO KING'S COLLEGE HOSPITAL AND TO THE WEST LONDON HOSPITAL.

THIS operation has been planned upon experiments performed on the dead, and upon one in a living, animal. Therefore I venture to hope that the present publication will be regarded only as a preliminary note, and not as the result of matured investigations. For, although the single operation upon a living animal was perfectly satisfactory, there are many points of importance that require full elucidation; and until further investigations into the matter are completed I would not care to say that the method here suggested is likely to emerge from a post-mortem and experimental success into a definite surgical procedure. This want of completeness will be manifest in the following description.

After the removal of the affected segment of the intestine by a section exactly transverse to the longitudinal direction of the bowel[1] and its V-shaped piece of attached mesentery the open ends of the gut lie requiring suture. Through all the coats forming the wall of each free end a longitudinal incision is made and in each case it should be situated exactly opposite that part of the bowel to which the mesentery is attached (Fig. 1). The length of each incision must

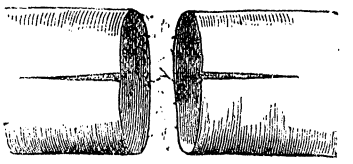

FIG. 1.

vary as convenience and necessity demand, but speaking generally it should at least be equal to the diameter of the tube at the seat of resection. These incisions allow the open ends of the intestine to be spread out in the shape of a fan and while in this state the separated serous surfaces can be exactly apposed as it were back to back (Fig. 2). An

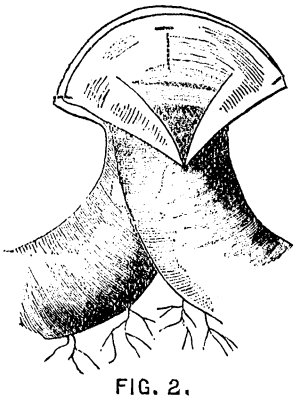

FIG. 2.

assistant should now gently keep the intestinal extremities in this accurately adjusted position during their final fixation. The first suture should fix in apposition the mesenteric attachments; the two next should likewise accurately join the respective extremities of the edge of the fan-shaped expansion (see Fig. 2). The rest of

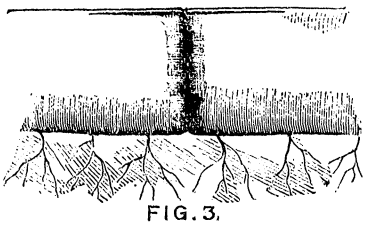

FIG. 3.

the stitches may now be inserted with greater exactitude. Each must be well tightened at the first knot, all coats of both ends must be transfixed by the silk bearing needles, and the needles and silk employed must be the finest that are compatible with safety. The ends are thus firmly joined and all that remains

[1] Subsequent experiments upon living animals may prove the necessity of making the actual section rather oblique or semicircular. In speaking to an authority upon this matter he thought this kind of section had been suggested before, but as I cannot find it I should be glad of the reference.

to be done is to suture the longitudinal incision by any of the well-known methods which the operator may prefer. Care must be taken that its edge be well sequestrated by the approximation of its serous surfaces, thereby placing the site of meeting of the four corners out of the realms of surgical importance, the site of the four corners obviously being at the centre of the longitudinal incision (see Fig. 3).

This method, besides allowing the possibility of joining intestinal tubes of the same diameter can also permit the union of the small to the large gut. Therefore, should it ever be necessary to remove the ileo-cæcal portion in cases of malignant disease, intussusception, strangulation, and so forth, this additional attribute may prove to be of some value. The only addition necessary to accomplish the junction occurs after the small intestine has been sutured to the colon by the method described above. Then there will be on each side of the joined intestines two equal sized superfluous flaps of the large intestine, A portion of each of these flaps can be cut away in a V-shape, so that the apex of the V is exactly in a line with the preliminary incision into the free end of the small intestine—in other words it should be opposite the meso-colic attachment. The remaining superfluous part of these two edges can be inverted by the Lembert's suture that is employed while sewing up the resulting longitudinal incision. The result will be that the colon tapers to its union with the ileum.

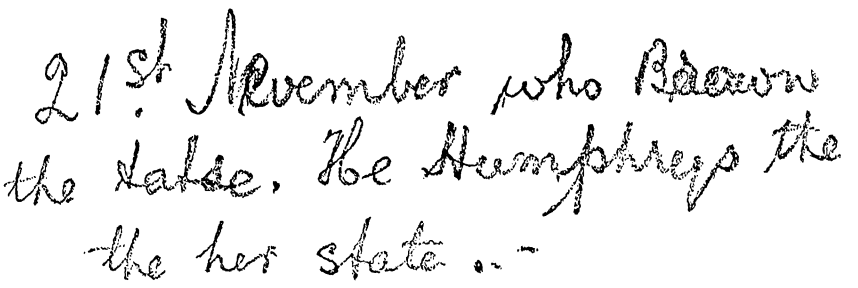
ILLUSTRATIVE CASES OF APHASIA.

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN., F.R.S. EDIN.,

PHYSICIAN TO THE EDINBURGH ROYAL INFIRMARY, LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, SCHOOL OF MEDICINE, EDINBURGH, ETC.

(*Concluded from page 1259.*)

CASE 12. *Sudden cerebral seizure due to embolic infarction in a man aged twenty five years; temporary loss of power in the right side of the face, right arm, and right leg; complete motor vocal aphasia; some, but comparatively speaking much less, agraphia; no word-deafness; no word-blindness; complete recovery of the power of writing; gradual but slight improvement as regards vocal speech; second embolic attack four months afterwards; increased paralysis of the right side of the face, of the right arm, and of the right leg; no increase of the motor vocal aphasia; marked increase in the agraphia; some word blindness; no word-deafness; death four years after the original seizure; necropsy*—This case is a typical example of motor vocal aphasia due to softening, the result of embolic infarction of Broca's convolution. There were two embolic attacks. As the result of the first attack, which occurred on Nov. 21st, 1892, there was temporary loss of power in the right side of the face, right arm and right leg, complete motor vocal aphasia, and some agraphia. When I saw the patient, on Dec. 6th, 1892, the paralysis of the face, arm, and leg had almost entirely disappeared. He could understand everything that was said to him. He could understand written questions. He could not express himself by spoken speech. He could not repeat what he was asked to repeat. He could not read aloud. But—and this is a very interesting and important point—he could express himself, though somewhat imperfectly, in writing; in short, his power of expressing himself in writing was very much less impaired than his power of expressing himself in spoken language. Between Dec. 6th, 1892, and March 1st, 1893 (the date of the second seizure), gradual improvement took place. The paralysis of the face, arm, and leg completely, or almost completely, disappeared. The patient regained the power of speaking in some (a very limited) degree, presumably by compensation, the right motor vocal speech centre taking on the function of the left motor speech centre (Broca's convolution), which had been destroyed. The power of writing was perfectly, or almost perfectly, restored (see letter written on Dec. 20th, 1893). On March 1st, 1893, a second embolic attack occurred. The paralysis of the right side of the face, right arm, and right leg was much more marked after this attack. The lower part of the face remained completely paralysed until the date of the patient's death (June 10th, 1896). After this second attack the motor vocal aphasia was not materially aggravated. I presume that this was due to the facts that Broca's convolution had been entirely destroyed as the result of the first embolic attack, and that the motor vocal speech which had been regained was being carried on by the motor vocal speech centre in the right hemisphere of the brain. After the second embolic attack the power of writing was much more markedly impaired, and the power of reading also became impaired. This was probably due to softening of the supra-marginal convolution, the angular gyrus, and the subjacent white tissue. The post-mortem examination showed:—1. That the patient was suffering from mitral stenosis and very free aortic regurgitation. The heart was very large, being both hypertrophied and dilated. 2. That there was an extensive old softening, evidently due to embolism of the left middle cerebral artery in the left hemisphere of the brain. The following parts in particular were affected: (*a*) Broca's convolution—this was completely destroyed; (*b*) a small portion of the posterior end of the second left frontal convolution; (*c*) the inferior end (about a fourth of the whole extent) of the left ascending frontal and ascending parietal convolutions—these parts were completely destroyed; (*d*) the anterior two-thirds at least of the upper (first) left temporo-sphenoidal convolution—this was completely destroyed; (*e*) the upper part of the anterior two-thirds of the second left temporo-sphenoidal convolution; (*f*) a portion of the anterior and inferior end of the left supra-marginal convolution—the softening of the cortex in this situation was much less extensive; and (*g*) a very localised area (on the surface) of the left angular gyrus. The extent of the softening in the subcortical white matter and the extent of the secondary degenerations which were present were not determined, for, as is stated in Dr. Muir's report, the brain, after being most carefully prepared (injected with Müller's fluid), was completely destroyed by an unfortunate accident. I have in the course of my career lost many interesting pathological specimens through the failure to obtain post-mortem examinations, but I have rarely, if ever, regretted the loss of any specimen so much as the loss of the brain in this most interesting and important case. In the absence of exact information regarding the extent of the lesion I shall not attempt to discuss the case in further detail. The more important points are:—1. The complete destruction of the motor vocal speech centre (Broca's convolution). There can, I think, be no reasonable doubt that Broca's convolution was completely destroyed at the time of the first embolic attack; the lesion was embolic; there was complete motor vocal aphasia after the first attack; and the defect in vocal speech was no worse after the second attack. 2. The fact that after the first attack (when, as I have just stated, Broca's convolution was presumably completely destroyed and complete motor vocal aphasia was established) writing was, compared with motor vocal speech, only slightly affected. Further, the power of writing was perfectly regained, while the power of speaking was only very imperfectly regained. These facts undoubtedly seem to show that the motor impulses connected with the initiation of the act of writing do not *necessarily* (and presumably, therefore, not *usually*) pass through Broca's convolution (the vocal speech centre as most authorities suppose).[1] 3. The absence of word-deafness notwithstanding the extensive destruction of the first temporo-sphenoidal convolution and of a portion of the second left temporo-sphenoidal convolution. Although the posterior end of the first left temporo-sphenoidal convolution was not destroyed one would have expected (if the auditory speech centre was entirely located in the left hemisphere) that the function of the auditory speech centre would have been at least temporarily disturbed—i.e., that there would have been some temporary word-deafness. 4. The complete and lasting paralysis of the right side of the face which presumably was due to destruction of the lower end of the left ascending frontal and ascending parietal convolutions. This is exceptional. 5. The partial word-blindness and agraphia which were developed after the second embolic attack. These were probably due to extension of the softening to the left supra-marginal convolution and (?) angular gyrus. 6. The constriction of the fields



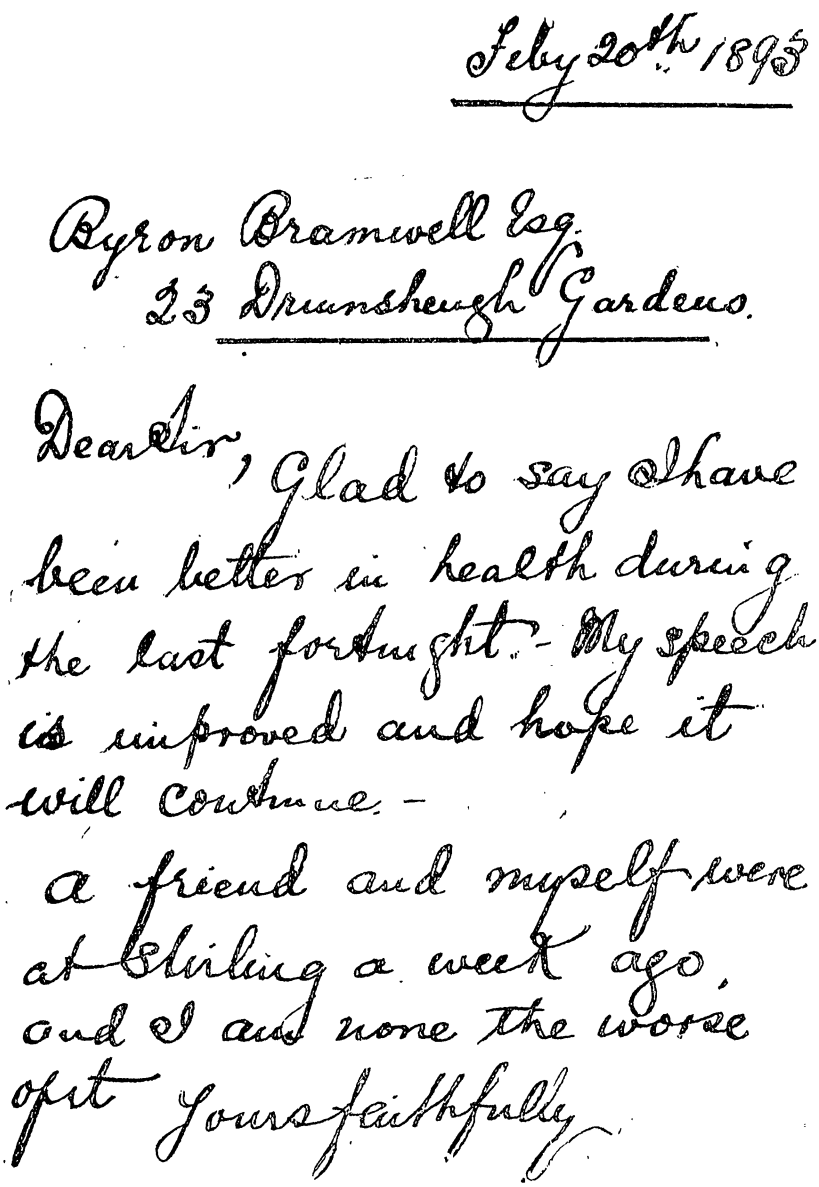
[1] I do not say the writing *speech* centre, for I agree with Déjerine and Mirallié in thinking that the balance of evidence is against the existence of a separate centre for written *speech*. The terms *writing centre* and *writing speech centre* are not, in my opinion, synonymous.

Hosted by Google

of vision. This is a point of some interest. I have observed the same condition in some other cases of word-blindness in which there was no hemianopsia. 7. The impairment of hearing in the right ear. This was presumably due to destruction of the first and second left temporo-sphenoidal convolutions. It seems to support the view that the anterior portion of the first and second temporo-sphenoidal convolutions is *the lower* auditory centre (centre for sounds and noises as distinct from speech sounds), while the posterior portion of the same convolutions is *the higher* auditory centre (the auditory *speech* centre). 8. That notwithstanding the complete motor vocal aphasia due to complete destruction of Broca's convolution, there was, up to the date of the second attack, absolutely no evidence of any intellectual or mental impairment.

The notes of the case are as follows. A man, aged twenty-five years, was sent to me by Dr. —— on Dec. 6th, 1892, suffering from motor aphasia. The attack had come on suddenly on Nov. 21st, 1892. For some time previously the patient had suffered from shortness of breath on going uphill, and other symptoms of heart disease. His mother stated that he had not had rheumatic fever or scarlet fever, but when eight years old he suffered from chorea, which was not, however, very severe or of long duration. He himself indicated that he has been short of breath for the last five years, but his mother doubted this. Two years previously he was refused by an insurance company. Until two or three years before he had been very active and strong. The family history is unimportant. The following history of the attack was partly ascertained from the friend of the patient, who was with him at the time when the attack occurred, and partly from the patient himself as soon as he was able to express himself in writing and by vocal speech. On Saturday, Nov. 18th, he got a chill whilst watching a football match. He remained at home on Sunday and the greater part of Monday. On Monday afternoon he went out and, his mother says, did not return till after twelve o'clock at night. (The patient strongly dissented from this statement, shaking his head and attempting to say "No." He indicated on his fingers that he came home at half-past ten.) On the evening of Tuesday, Nov. 21st, he went out with a friend with the object of seeing the stage manager at the Lyceum Theatre, Edinburgh. He waited with his friend in the street for about half an hour, feeling very cold. Just before the seizure (11 P.M.) he said to his friend, "He is taking a long time to come out"; he then staggered back to the theatre wall, his feet seemed to twist under him, his hat fell off, but he did not fall. His friend, seeing his face screwed up, thought he was laughing. He did not lose consciousness, but he was unable to speak. He sat down, waited for a few minutes, and was then taken home to his lodgings in a cab. Dr. —— was sent for and came to see him shortly afterwards. On examination it was found that he had lost the power in his right arm, right leg, and the right side of the face, and that he was unable to speak. He was right-handed. Next morning his mother found him quite conscious, but speechless. He was able to understand everything that was said to him. He wrote his initials, but could not fill in the full names. During this, the first day after the attack, his mother states that he said the words "no," "chronicle," and "conscience." His speech had not improved since, but the paralysis of the face, arm, and leg had almost disappeared. On Dec. 6th, when I first saw the patient, I found him to be a tall, big, well-made man. The heart was very large, the apex being situated in the sixth and seventh interspaces, two and a half inches beyond the nipple line. A loud diastolic murmur was heard in the aortic area and all up and down the sternum. At the apex there was a presystolic murmur which appeared to be independent of the aortic diastolic murmur. The pulse, which was quick (120 per minute), was jerking and collapsing in character, but less markedly so than one would expect in an uncomplicated case of very free aortic regurgitation. The characters of the pulse and of the sphygmographic and cardiographic tracings (which were taken at a subsequent visit) were suggestive of a double lesion—mitral stenosis as well as aortic regurgitation. The paralysis of the right side of the face, arm, and leg had almost entirely disappeared. The pupils were widely dilated. The patient's intelligence was obviously intact. He looked sharp and alert. He seemed to be able to understand perfectly everything that was said to him. There was no derangement of the auditory speech centre. The patient was carefully tested in a variety of ways so as to elicit this point. He was almost totally unable to express himself in spoken language. The only words which he was able to make use of at this, my first, examination—and they were expressed with great effort and difficulty—were "yes" and "no." He used these words quite correctly—i.e., in a propositional sense and not merely reflexly or automatically. He could not repeat anything which he was asked to repeat. He could not read aloud. He apparently understood written language perfectly. When asked in writing to put out his tongue and perform similar acts he immediately did so. He could write very much better than he could speak. *He carried a note-book about with him for this purpose;* but his mother said that he could not always write what he wanted to say. He made mistakes in writing. Sometimes he wrote letters which did not make a word at all, and then he got irritated if they could not be read. His power of writing varied, his mother said, very much from time to time. If he was agitated or excited—and since his illness he had been very excitable and emotional—he could hardly express himself in writing at all; at other times he could write well. She volunteered this statement when she saw the following account (which she stated was very much worse than his writing when unagitated), which I asked him to write of the mode of onset of the attack. I asked him his name, his age, and the day of the week. He could not answer these questions in spoken language, but when asked to write the answers he produced his notebook and immediately wrote down the answers quite correctly. The letters were perfectly formed. I then asked him to write an account of what took place at the time of the seizure. He said, "No, no," shaking his head emphatically as a sign of dissent and at the same time pointing to his right hand and leg, apparently meaning to indicate that he could not do so because he was paralysed. I then pressed him to do the best he could. He wrote the following: "21st November who Brown the tatse. He Humphreys the the her state" (see Fig. 22). His mother explained that Brown was the name of the friend with whom he went to the theatre to see the manager named Humphreys. Iodide of potassium, mercury, and digitalis were prescribed. On Dec. 14th the patient was much *in statu quo*. He did not say anything more; but was writing a little better. On the 21st he looked better. His mother said he was not so blue. She also said that before he started to come to see me on this date he said the word "ten." This was the only word except "yes" and "no" which he had uttered since I first saw him. He was anxious about catching the car in order to keep his appointment with me. He knew he must get the car at two o'clock in order to be in time; it was ten minutes to two before his mother was ready to start—it was then that he said the word "ten." On Jan. 14th, 1893, his mother said that since the last visit he had spoken more, but was only able to say individual words, never sentences; he had said the words "despatch," "Mid-Calder," "Newcastle," "morning," and "good afternoon." He looked much better. On Feb. 2nd he was distinctly better; he could say a few short sentences, but very imperfectly, and could write much better. The heart was much *in statu quo*. On the 20th he wrote the letter

FIG. 22.



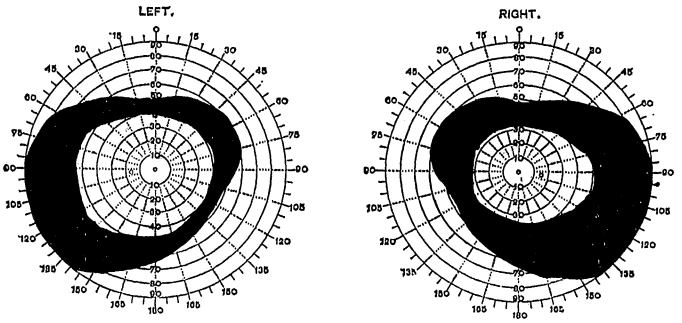
Facsimile of patient's written statement describing the onset of his illness.

Hosted by Google

which is reproduced in Fig. 23; it will be seen that the writing and expression were practically as good as they could be. His speaking had improved to some slight extent, but the motor vocal aphasia was still very marked (the slight improvement which had occurred was not greater than might reasonably be accounted for by substitution and compensation, the motor vocal speech centre in the right hemisphere taking on the action of the motor vocal speech centre in the left hemisphere—Broca's convolution—which had been entirely destroyed).

The facts that the writing was from the first so much less affected than speaking and that the power of writing was regained so much more quickly than the power of speaking are of great interest and importance, for in most cases of motor aphasia due to destruction of Broca's convolution the writing is as much affected as (proportionately to) the speaking. This case seems to disprove the view that the nerve impulses concerned in the act of writing necessarily pass from or through the motor vocal speech centre in order to reach the writing centre; for if the nerve impulses which put the writing centre into action necessarily pass through the motor vocal speech centre (Broca's convolution) one would expect that in a case such as this, in which the motor aphasia, evidently due to complete destruction of Broca's convolution, was complete, there would have been complete agraphia. There is no reason to suppose that in this case the motor aphasia was due to a lesion situated in the conducting fibres passing from Broca's convolution to the bulbar nuclei. The lesion was evidently embolic; Broca's convolution was completely destroyed at the time of the necropsy, and there is every reason to suppose that it was completely destroyed after the first seizure. In cases of motor aphasia impairment of writing may theoretically be due: (*a*) to the fact that the lesion of the vocal speech centre deranges the action of the visual speech and writing centres, which are themselves unaffected by the lesion; or (*b*) to the fact that the lesion involves the writing centre (I do not say writing *speech* centre) as well as the motor vocal speech centre; or (*c*) involves the fibres connecting the motor vocal speech centre and the writing centre; or (*d*) the commissural fibres connecting the visual speech centre with the writing centre (through which I presume the nerve impulses which put the writing centre into action usually pass).

FIG. 23.



Letter written without assistance by the patient (Case 12) on Feb. 20th, 1896. (Facsimile.)

On March 1st, 1893, he had a second seizure; it came on through the night; he felt, he says, a numb, powerless feeling in the right side. When the landlady went into his room to call him at 7.30 next morning he held up his right arm to show her that he had had another attack. Dr. —— and his mother were immediately sent for. The right side of the face, the right arm, and, to a less extent, the right leg were affected. He was quite conscious when his mother saw him. She said that his speech did not seem to be more affected than it had previously been. On April 7th the patient came to my consulting room again. There was then complete paralysis of the lower part of the right side of the face. (This persisted up to the date of the patient's death—three years afterwards.) The paralysis of the right arm and leg was distinctly increased, but much less so than the paralysis of the face. The grasping power as tested by the dynamometer was in the left hand 110 and in the right 25. He dragged the right leg a little. He said that he did not feel a touch on the right side of the face or on the right arm, but that he did feel it in the right leg, though less distinctly than in the left. He also said that his hearing was less distinct in the right than in the left ear. (This is interesting, since the anterior two-thirds of the first temporo-sphenoidal convolution and part of the second temporo-sphenoidal convolution were found to be completely destroyed at the necropsy.) Smell was equal on the two sides. His heart was worse. The pulse, after undressing, numbered 132 pulsations per minute; before undressing it was 96; some beats did not reach the wrist. The motor vocal aphasia did not appear to be in any way worse than it was before this second embolic attack, but there was now very considerable word-blindness and very decided agraphia. The power of writing had, it must be remembered, been entirely regained before the second embolic seizure. At this visit the fields of vision were

Hosted by Google

carefully mapped out. The perimeter chart shows that they were constricted in both eyes (see Fig. 24), the right field being more constricted than the left. Further, the patient was very much quicker in his answers when the left field was being taken. He was advised to continue the strychnine and digitalis, which he had been taking. By May 16th there had been little change in the patient's condition. The paralysis of the right side of the face remained complete; the paralysis of the right arm and right leg was decidedly better; the aphasic symptoms were unchanged. On March 27th, 1894, soon after the last note (May, 1893), the patient caught cold looking on at a football match and had a severe attack of bronchitis; for some days he was very ill. Since recovering from this attack he had been wonderfully well. He was now very blue in the face. The heart seemed even larger than it was before. The valvular lesions appeared to be unchanged. The action was very quick. He had been speaking a little better since the date of the last note, but his writing was bad because, he said, he was not able to use the arm at the wrist. The face was still drawn to the left side. The right arm and leg were less paralysed. The grasping power as tested by the dynamometer was in the right hand from 65 to 70 and in the left hand 150. He read the following sentence from a telegraph form with only two mistakes — "transmission" and "regulations":— "Notice. — This telegram will be accepted for transmission subject to the regulations made pursuant to the 2nd Section of the Telegraph Act, 1885, and to the notice printed at the back thereof." The word "regulations" he said was "heretofore." He wrote his name correctly. On Nov. 19th, 1894, and June 5th, 1895, he sent me the following letters:—

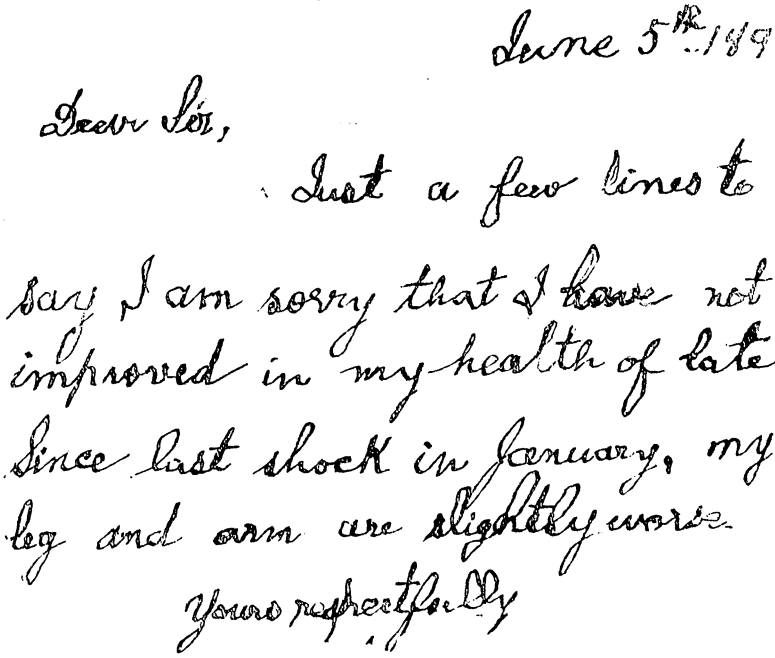
FIG. 24.

Perimeter chart showing the fields of vision in the patient (Case 12) on April 7th, 1893.

"BYROM BRAMWELL, Esq.

"November 19th, 1894.

"DEAR SIR,—Dr. —— asked me to write you a letter. Two years have elapsed, I am no better, and little worse. The heart beats quickly and slowly, and when I laugh my face goes to the side. It is very kind of you to enquire for me.



"Yours sincerely,

"————."

On June 5th, 1895, the patient wrote the letter reproduced in Fig. 25.

His mother afterwards told me that he had not written these letters entirely by himself. He asked her to help him with them; she refused, knowing that I wanted to see exactly what he could do for himself. He subsequently admitted that a friend (Mr. B.) had helped him. As the point was of great importance I made a point of seeing and cross-examining the friend (Mr. B.) who had helped the patient. Mr. B. told me that they concocted these letters together, that he (Mr. B.) then wrote them down, and that the patient then copied them. Mr. B., the patient's mother, and the patient himself all state definitely and positively that the letter written on Feb. 20th, 1893 (prior to the second seizure), was entirely and spontaneously written by the patient himself. I have no doubt whatever that this was so, for in addition to this letter written to me the patient, prior to the second attack, frequently wrote memoranda, &c. On April 9th, 1896, the patient was seen at his own house. He had not been at all well since the beginning of the year. The legs were very œdematous. His colour was bad, yellow, and somewhat blue. He was thin. The tongue was clean. The heart's action was very irregular, the enlargement being greater than ever. The pulse was weak, quick, and less bounding than it used to be. The urine was dark coloured. He spoke perhaps a little better than when I saw him last. The right side of the face was still markedly paralysed; when he smiled the face was drawn right over to the left side. The grasping power of the right hand was good, but he seemed to have difficulty in making fine movements, such as writing with the right hand; he could hold a pencil securely, but he wrote very badly. He usually wrote with the left hand. When I went into his room he was copying some business particulars out of his note-book. The condition of the speech functions, which were carefully tested on this visit, were as follows. He seemed to understand perfectly everything that was said to him. He was able to read fairly well, but his mother thought he did not always understand what he read. She said that he soon got tired and exhausted. At this visit he made some curious mistakes in reading. The individual words were, for the most part, read correctly, but not always, and he seemed to have special difficulty in reading some of the short words. For example, in reading the following sentence: "Read the verdict of our patrons on our efforts to please," he read everything correctly except the words "the," "on," and "patrons"— "the," he said, was "and," twice over; "on," he said, was "and," and then corrected himself, saying, "no, no," but he could not suggest the right word; "patrons," he said, was "patronage"; and the word "on," he said, was "to." When asked to read the individual letters composing the word "in" he was unable to do so. He could not suggest anything for "i"; he obviously knew "n," because he traced it on his thigh with his finger—in other words, his mental conception of the form of the letter "n" was perfectly retained, and yet he could not name it. He said, "I will write it down; I cannot explain it." He wrote it down. I asked him what it was; he could

FIG. 25.

Facsimile reproduction of letter written (with assistance) by the patient on June 5th, 1895.

Hosted by Google

not name it. He said, "I cannot explain it." He was then asked to write the words "the," "in," and "on," and he wrote them quite correctly both with the right and also with the left hand. He also wrote the words "the," "in," and "on" (which he had not been able to name in reading) quite correctly to dictation without any hesitation. He was then told to ask me a question in writing. He thought some time, and then said, "How do you do?" I asked him to write it down; he said, "I cannot." He was pressed to write it, but said again and again, "I cannot." I then asked him, "Can you write your name down?" He said, "Yes." I said, "Let me see." He wrote it correctly with the right hand. I then asked him how it was that he was able to write his name and not other words, and he said, "Oh! ——, common name." I then asked him to try to write with the left hand, "How do you do?" He wrote "the" and then stopped; he said he could not manage it. I then asked him to suggest another sentence, and he said, "—— is a good man," naming the practitioner who sent him to me. I told him to write it down. He said, "I cannot." He tried, but could not. I then wrote it down, and he at once was able to read it. He then copied it readily enough. He then said, "You are a good man." I asked him to write it down. He wrote, "Bramwell is a ——" (he was beginning to write "good," and I told him to write "nice doctor" instead of "good man," and he wrote the words "nice doctor" down quite correctly). When he was asked to write down, "How are you?" he wrote the words, "You are is." Asked to write, "Mad dog," he did so correctly. He was next asked to write "24" in figures; he did so without any hesitation quite correctly. I asked him how it was that he could not write many of the things that he could read. He said, "The mind—there it is," making a circle with the forefinger of his left hand on the top of his head.

The patient died on June 10th, 1896. The post-mortem examination was made by Dr. Muir on June 11th, 1896, Dr. —— and myself being present. Dr. Muir's report is as follows:—

"*Notes of Post-mortem Examination, June 11th, 1896.*—*Brain:* On removing the dura mater a large softening was found on the left side involving the region around the commencement of the Sylvian and Rolandic fissures. It had the usual appearances of a softening of very long standing and implicated the following parts. The posterior third of the inferior frontal convolution was completely destroyed. The adjacent part of the posterior end of the second frontal was slightly softened. The lower fourth of the ascending frontal and ascending parietal convolutions was destroyed, the line of softening running sharply across them. There was also partial softening of the supra-marginal convolution in its lower anterior part, especially immediately behind the ascending parietal, where the softening reached a higher level than in the latter; but the greater part of the supra-marginal appeared to be well preserved. The superior and middle temporo-sphenoidal convolutions were extensively affected, being completely destroyed in their anterior two-thirds, with the exception of the lower margin of the middle temporo-sphenoidal. There was also a small patch of softening about a third of an inch in diameter in the postero-inferior part of the angular gyrus, otherwise this convolution appeared healthy. The convolutions of the island of Reil were also more or less softened. The left middle cerebral artery was closed and converted into a firm fibrous cord. The brain was injected with Müller's fluid and kept for further examination, but, unfortunately, during alterations in the pathological department of the infirmary the jar containing it was broken by workmen and the brain destroyed.

"*Heart.*—The heart was enormously enlarged, both sides being affected. It measured almost eight inches in greatest diameter from the apex to the border of the right auricle and nearly six inches at right angles to this. The aortic valve was incompetent and somewhat stenosed, its diameter being eight inches. The segments showed chronic endocarditis with nodular thickening of their margins and some adhesion at their extremities. The mitral valve was markedly stenosed. Its margins were irregularly thickened and much indurated, and there was extensive calcareous deposit, especially in the form of a large irregular plate at the left side. Another irregular calcareous bar ran across from the side of the valve to the interventricular septum. The margins of the orifice were thus very rigid and irregular. The chordæ tendineæ were thickened and shortened and partly adherent. The pulmonary orifice was normal, as was also the tricuspid, with the exception of being dilated, measuring 1·85 inches. The left ventricle was greatly dilated, measuring 4½ inches in length, and being proportionately widened; its wall measured in thickness from five-eighths to one-quarter of an inch, being comparatively thin in the lower part. The columnæ carneæ were considerably atrophied at places and the endocardium somewhat thickened. The right ventricle was also much dilated, measuring four and three-quarter inches in length, and was also hypertrophied, the greatest thickness of the wall being a quarter of an inch. Its columnæ carneæ were large and comparatively well nourished. Both auricles were extremely dilated and the endocardium of the left was thickened. The weight of the heart was 21b. 3oz. The right side was enormously distended with masses of dark clot and there was a thrombus in the right auricular appendix. A few degenerative patches were present in the aorta immediately above the cusps, but beyond that the intima was healthy."

Concluding remarks.—I possess detailed notes of several other cases of aphasia in addition to the twelve cases which I have now recorded. Some of these are still under observation and may, perhaps (provided that the clinical details are supplemented by post-mortem examination), be published at some future date; others, in which there has been no necropsy, have been omitted, since they do not present any points of novelty or special interest. One of my chief objects in publishing the twelve illustrative cases recorded above is to support the view that the right hemisphere must be regarded as forming an active part of the nervous speech mechanism; in other words, that the so-called speech centres and speech faculties are bilaterally represented. This bilateral representation seems to me most obvious in the case of the auditory speech centre; but there is, I think, every reason to suppose that it also holds good in the case of the visual speech centre and the motor vocal speech centre. I say most *obvious*, for it must be remembered that because complete aphasia of whatever kind (word-blindness, word-deafness, or motor vocal aphasia) results from destruction of one of the speech centres (upper temporo-sphenoidal convolution, angular gyrus, or Broca's convolution) in the left hemisphere, it does not necessarily follow that in a condition of health the corresponding centre in the right hemisphere is inert and inactive so far as all speech function is concerned. Such a result—the production of complete word-deafness, word-blindness, or motor vocal aphasia after destruction of the auditory speech centre, the visual speech centre, or the motor vocal speech centre in the left hemisphere—merely shows (*a*) that the speech centre in the left hemisphere which was destroyed, and in consequence of the destruction of which word-deafness, word-blindness, or motor vocal aphasia (as the case may be) has resulted, was (while the patient was in a condition of health) the active, "leading," or "driving" speech centre; and (*b*) that the corresponding centre in the right hemisphere was in that particular case (and this, of course, is the usual condition) unable of itself to immediately carry on the speech function, which was lost when the driving centre was destroyed. It does not show that the corresponding centre in the right hemisphere is inert and altogether inactive—i.e., has no speech function. It is true that in the present position of our knowledge and with our present methods of observation it is rarely possible to demonstrate this activity; but the facts that in certain cases of disease the apparently inactive centre in the right hemisphere is capable of being trained to take up and carry on the function of the "driving" centre in the left hemisphere which was destroyed, and (as Dr. Bastian has pointed out) that the corresponding centres in the right hemisphere are structurally as well developed, or for all practical purposes as well developed, as the "driving" speech centres in the left hemisphere, in my opinion strongly suggest that the corresponding centres in the right hemisphere must perform some sort of speech function (which is usually no doubt carried on in conjunction with and, as it were, in subordination to—i e., in other words, in the case of voluntary or intellectual speech, at all events, not independently of—the function of the "driving" centres in the left hemisphere). And further, I have tried to show that this view is actually supported by the facts of disease. I have argued that, in some cases at all events, the auditory speech centre in particular, and probably also the other

Hosted by Google

speech centres (visual speech centre and motor vocal speech centre), are sufficiently educated and active to take up and independently carry on the speech function when (immediately) the (usually) driving speech centre in the left hemisphere is destroyed—i.e., without further education and training. I have further elaborated this view as to the bilateral action and representation of the speech functions (which has also been so ably argued by Dr. Charlton Bastian in his recently published Lumleian Lectures) in my Systematic Lectures on Aphasia, which have been typewritten for many months, and which will I hope before long be published. On some other points I have also independently arrived at some of the same conclusions which Dr. Bastian has advanced. Thus I have argued, contrary to the usually accepted opinion, that the nervous impulses which excite the act of writing pass directly from the visual speech centre to the writing centre, and not, as is usually supposed, indirectly through the motor vocal speech centre (Broca's convolution). Cases 1 and 12 seem to show this, and Case 12 seems to prove that complete destruction of Broca's convolution does not, as most authorities believe, necessarily entail agraphia. Further, in commenting on Case 11 I have suggested the novel and important view, which has been more fully elaborated by Dr. Bastian in his recent lectures, that under certain circumstances the auditory speech centre in the right hemisphere may act upon, and through, the motor vocal speech centre (Broca's convolution) in the left hemisphere. I presume that if the right auditory speech centre is able to take up and carry on the function of the left auditory speech centre (the usually driving auditory speech centre) immediately after the left auditory speech centre has been destroyed, that the nerve impulses, in the great majority of cases at all events, probably pass out through the *left* motor vocal speech centre (Broca's convolution), and not through the *right* or motor vocal speech centre, since in most persons, at all events, the right motor vocal speech centre can only "drive" after it has been slowly and laboriously educated to do so. In my Systematic Lectures I have pointed out in more detail than it was possible to do in commenting on individual cases the fundamental importance of this bilateral representation of the speech centres and speech faculties, and of these round-about modes of action, so to speak, for the purpose of compensation and the restoration of the speech functions in the various forms of aphasia produced by disease.

Edinburgh.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The eighth meeting of the session was held on May 12th, in the Medical Library of University College, Bristol, Dr. Harrison being in the chair. Mr. Ewens showed a case of Congenital Deficiency of both Fibulæ with extreme calcaneo-valgus, remedied by tenotomy and instrumental appliances, and Professor Fawcett and Mr. Rigg remarked on the case.—Mr. Morton showed a patient from whom the Head of the Tibia had been excised for Myeloid Sarcoma and the Shaft screwed to the Lower End of the Femur, and Mr. Ewens and Dr. Swain made remarks on the case.—Dr. Fyffe read notes on some of the Infectious Diseases of Public Schools, Dr. Harrison, Dr. Shingleton Smith, Dr. Symes, Mr. Taylor, Dr. Skerritt, Dr. Parker, Dr. Edgeworth, and Mr. Morton joining in the discussion.—Dr. Shaw made some remarks on a case of Hæmophilia with Joint Lesions, and Dr. Swain, Mr. Ewens, Mr. Fendick, and Dr. Parker discussed the case.—Dr. Parker described a case of Lead Poisoning presenting Hæmato-porphyrin in the Urine.

A DAY OF REST IN THE COUNTRY FOR NURSES OF LONDON HOSPITALS AND METROPOLITAN INSTITUTIONS.—In the summer of last year an opportunity was provided for such of the nurses of the metropolis as could be spared and were so disposed to spend a quiet day at Hertingfordbury. Three short services were arranged at intervals during the day, allowing the nurses full opportunity for enjoying the country. Hospitality was offered so that the actual expense to each nurse did not exceed a few shillings, being the cost of the return fare from King's-cross. A similar invitation has been given for Thursday, June 3rd, when the Bishop of Wakefield has kindly promised to give the address at each service. Any information as to details may be obtained from the secretary of the Hospital Chaplains' Union, the Rev. A. G. Locke, St. George's Hospital, who is acting officially in carrying out the arrangements, or communication may be made to Canon Burnside, rector of Hertingfordbury, Hertford.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

FEVER ON THE WEST COAST OF AFRICA.

BY DUNCAN J. CADDY, M.D. DURH.,
H.M. COLONIAL MEDICAL SERVICE (RETIRED).

ON Oct. 6th, 1896, the captain of a steamship then lying at Akassa, River Niger, West Coast of Africa, sent for me at 2 P.M. complaining of feeling hot and feverish and of a severe headache, and upon examination I found his temperature registered 104° F., so I at once ordered him to bed and had him well wrapped up in blankets and covered with an eiderdown quilt to produce diaphoresis, at the same time prescribing three grains of subchloride of mercury and a mixture of half a drachm each of bromide of potassium and carbonate of ammonia, one drachm of ipecacuanha wine, one drachm of phenazone, with water to six ounces; dose, one ounce every three hours; with an evaporating lotion for his head, which was kept well fanned, no ice being available. At 4 P.M. his condition was easier and less restless, diaphoresis having commenced and the temperature having fallen to 101°. I then administered one drachm of spirit of nitrous ether in one ounce of water, and at 5 P.M. he was perspiring profusely, and he drank a cup of hot tea; his temperature still, however, remaining at 101°. I remained up with him during the night, and he appeared to become much better, taking his mixture at regular intervals, his temperature sinking to 99 5° until the following day (the 7th) at 9 A.M., when it was 99°, and his bowels acted freely. At 12 noon his temperature registered 99·5°, and this continued the same until 3 P.M., when I gave him twenty grains of sulphate of quinine. At 4 P.M. his temperature was 100° and he was quite cheerful and expressed himself as feeling greatly improved and took another dose (five grains) of sulphate of quinine, when he slept until 8 P.M., at which hour he awoke and was given a further ten grains. His temperature did not vary until midnight, when it rose to 100 5°, and another ten grains of the sulphate of quinine and some hot beef-tea were given. At 3 A.M. on the 8th his temperature had risen to 102° and he took some more beef-tea, and I surrounded him with hot-water bottles and placed more wraps over him, when he perspired profusely. At 3.30 A.M. his temperature was 103 5°, and he drank some soda water and milk and took beef-tea at intervals. At 3 45 I gave him a hypodermic injection of ten grains of sulphate of quinine dissolved in a sufficient quantity of diluted hydrobromic acid and water, this being injected into four different places. At 4.30 A.M. the temperature rose to 105 5°, the pulse being 110, quick, and full, and he took two ounces of champagne with soda water, his breathing at this time being short and very hot. At 4.45 A.M. his temperature was 106° and he vomited half an ounce of dark blood and became anxious, saying he was convinced he would die; his face became congested and flushed, his skin swollen, cyanotic, burning hot, and dry. The conjunctivæ were injected and the dyspnœa increased. He was now rubbed all over with dry mustard, and hot beef-tea was administered, which caused the skin to act again, and he perspired freely. At 5 A.M. his temperature was 107°, at 5.15 A.M. 107·6°, at 5.20 A.M. 107·9°, and he became delirious and struggled violently, having to be held down in his berth, while the dyspnœa became intensified, and he presented a very cyanotic appearance, his lips becoming much swollen. At 6 A.M. his temperature registered 109°, at 6 15 A.M. 110·5°, and at 6.40 A.M. 111°, when he had a severe rigor, dying at 6 45 A.M., at which time his temperature rose to 111·5°, rigor mortis setting in ten minutes after death. His urine was rather scanty during the last few hours, but otherwise it was normal.

The points in this case which appear worthy of notice are the fact that the patient was quite free from delirium up to the time his temperature became 107 9°, and the rapidity with which his temperature rose between the hours of midnight and 6.45 A.M.—i.e., from 100·5° to 111·5°—and the height which it attained. I have to thank Mr. Edward

CASE OF RASH RESEMBLING SCARLET FEVER.

By LOUIS E. STEVENSON, M.B., B.C. CANTAB.

ON Oct. 18th, 1894 I was called to see a child said to be suffering from scarlet fever. Neither pyrexia nor angina was present. There was a rash covering the neck, the chest, most of the back, and the abdomen down to the level of two inches or so below the umbilicus. It had a remarkable resemblance to the rash of scarlet fever, showing a uniform pink ground dotted thickly over with scarlet points. At the upper and lower edges of the eruption there were isolated scarlet points. There was no rash anywhere else. The limited area of rash and its almost sharply defined upper and lower edges were suspicious, and I asked the mother if the child was wearing new flannel. She said not, but she informed me that she had washed the child's woollen under-vest with water to which some paraffin oil had been added, and on examination the garment in question had a strong odour of that oil. The rash quickly faded away, there was no desquamation, and although there were two or three more children in the house who had never had scarlet fever, no more cases of rash occurred. The house was also a very insanitary one, so that I think there can be little doubt that this was a case of artificial rash caused by irritation from paraffin oil.

CASE OF PURPURA HÆMORRHAGICA FOLLOWING "MALTA FEVER" OR "MEDITERRANEAN FEVER."

By G. E. MACLEOD, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,
LATE ASSISTANT PHYSICIAN, DISTRICT ASYLUM, INVERNESS.

THE following account of a rapidly fatal case of purpura hæmorrhagica occurring during an early period of convalescence from an acute attack of "Malta fever" or "Mediterranean fever," which came under my notice a few months ago, may be of interest to some of the readers of THE LANCET. The patient, a naval officer, while stationed at Malta, contracted a sharp attack of so-called "Mediterranean fever," for which he was under treatment on the island for about seven weeks, being invalided home at a very early period of convalescence by his medical attendants. When I first saw him he was in an extremely emaciated and very weak condition, having to be carried on board the steamer, and being quite unable to raise himself from the horizontal position without assistance. He spoke with difficulty and seemed to be in great mental distress, constantly brooding over his troubles, and taking a very gloomy view of his condition. His face was pale and exsanguine, the tongue was thickly coated and tremulous, and the bowels were obstinately constipated. The radial pulse was very weak and rapid and the temperature was slightly subnormal. On his arrival on board he was immediately given a little stimulant and placed on a nutritious liquid diet of beef tea and milk, administered alternately at short intervals, and a mixture containing iron and arsenic was prescribed, the bowels being freely opened by enema. Under this treatment the patient improved considerably, and when seen early the next morning was found to be much brighter and more cheerful, having had a good night's rest. The pulse was now much stronger and less rapid and the temperature normal (98·4° F.). His face was less anæmic in appearance and his hands less tremulous, and he seemed to take much more interest in his surroundings, remarking how much better he felt, and that he thought the voyage was already doing him good. This improvement continued for two days, during which time there were no particular symptoms needing attention, the patient going on satisfactorily. On the morning of the third day, however, it was noticed for the first time that several small purpuric spots had made their appearance on his legs and forearms, and although he did not complain of feeling any worse he was decidedly weaker and less cheerful than on the previous day. The temperature was 99° and the pulse 80. Towards evening the patient had a slight attack of epistaxis, followed in about three hours' time by a much more severe one, the blood escaping freely in spite of the usual milder treatment, and finally necessitating plugging of the anterior nares, which succeeded in stopping it for a time. (The posterior nares were also carefully examined, but no blood could be seen escaping through them.) Shortly after this a general sanguineous oozing commenced from the mucous lining of the mouth, the blood collecting round the bases of the teeth and then being swallowed and vomited, thus simulating hæmatemesis. The patient was kept absolutely at rest in the horizontal position in a cool room, and liquid extract of ergot was administered in thirty-minim doses, astringent mouth washes being used frequently, which, however, seemed to have merely a temporary styptic effect. As there was no hæmatemesis excepting the spurious form of it above alluded to, liquid nourishment was still given by the stomach in small quantities and iced as a precautionary measure. An interval of about two hours now elapsed, during which there was practically no bleeding at all, but after this it recommenced with redoubled severity, hæmaturia being now noticed for the first time, the blood (which was of a bright red colour) being passed towards the end of micturition, pointing to vesical hæmorrhage. Ergotin was now injected hypodermically and other astringents freely administered, but in spite of all treatment the patient rapidly grew weaker and weaker, passing into an extremely anæmic state, and finally sinking from loss of blood and exhaustion. The exceptionally malignant form of the disease as exemplified by this case makes it not devoid of interest, resembling as it does so closely a rapidly fatal type of hæmorrhagic purpura (purpura fulminans) alluded to by Roberts in the ninth edition of his "Theory and Practice of Medicine." The pathology of the purpura, which occurs during convalescence from fever, is interesting; thus Immermann, as quoted by Fagge, in the third edition of his "Text-book on the Principles and Practice of Medicine," suggests that "it is possibly due to the circumstance that the recovery of the minute vessels is sometimes retarded beyond the time at which the volume of the blood is restored and the heart regains its vigour." It would be extremely interesting to know in this connexion whether the definite micrococcus which, according to Dr. David Bruce, is to be found in the organs in every fatal case of "Malta fever" is capable of producing those changes in the blood and small vessels to which morbus maculosus is generally attributed.

Guilford-street, W.C.

ARREST OF DEVELOPMENT OF THE CRANIAL BONES

By HENRY GEORGE DIXON, M.R.C.S. ENG.,
L.R.C.P. IREL.

ON the evening of June 30th, 1895, a primipara was delivered without assistance of a seven months' female child, who was found dead in bed attached to the placenta, which was in the vagina. The trunk and lower extremities presented no peculiarites. There appeared to be no neck, the absence of several cervical vertebræ giving the face the appearance of being sessile on the thorax. The eyes, which were very prominent, had the appearance of being placed on the summit of the cranium, which sloped away backwards immediately behind them. There were no upper orbital plates, the frontal bone being absent, as were also both parietals and the greater part of the occipital and temporal bones. At the back of the eyes and nose was a bony mass requiring the use of the saw to divide it; it was about three-quarters of an inch thick and contained a small cavity in which there was about half a drachm of dark-red matter of the consistence of marrow. It appeared as though the basilar processes of the occipital and sphenoid and the petrous portions of both temporals had coalesced and grown together. The spinal canal was patulous at its upper extremity; there the skin ceased, the bony mass being covered by a dark-red grumous substance. Both lungs floated in water. The mother asserted that the child, whose length was twelve inches and three-quarters and weight one and three-quarter pounds, was stillborn. I presume that the development of the bones forming the vault of the cranium did not advance beyond the membranous stage, and that the membrane gave way during birth

KING'S COLLEGE HOSPITAL.

A CASE OF CHRONIC INTUSSUSCEPTION; RESECTION; RECOVERY.

(Under the care of Mr. BOYCE BARROW.)

THE following case is a very typical instance of chronic intussusception, and is of interest not merely because it was the result of tuberculous ulceration, though that is by no means common, but also on account of the use of Murphy's button. At the present time a great deal of difference of opinion exists as to the value of the button, some surgeons look upon it as the quickest and one of the safest methods of uniting two portions of bowel, while others consider the button to be a most dangerous instrument. There is probably much truth in both views. It cannot be disputed that by means of the button two pieces of bowel can be very rapidly united, and that in many cases the patient recovers without any untoward symptoms; but it is equally certain that cases have occurred where the button has itself led to a fatal result either by ulcerating through the bowel wall or by causing intestinal obstruction. And in many other cases the button remains so long within the bowel as to give rise to anxiety. In the present case the union must have been speedy and perfect in spite of the protrusion of some mucous membrane. For the notes of the case we are indebted to Mr. William Turner, surgical registrar.

A boy, eleven years of age, was admitted into King's College Hospital on Feb. 24th, 1897, complaining of attacks of pain in the abdomen, accompanied by vomiting. His family history was good, his father and mother being healthy, and no history of the occurrence of phthisis in any member of the family could be obtained. The patient himself had never had any illness of importance. The following history of his present illness was obtained. Rather more than two months before admission he had complained of pains on the right side of the abdomen; these pains were griping in character and lasted for about a minute. At first they recurred about once a week, but the intervals of freedom from pain diminished in length, and the pains lasted a longer time. For the last day or two before admission they had recurred as frequently as every twenty minutes, and lasted quite three minutes. The patient had noticed that during an attack of pain a swelling appeared on the right side of the abdomen, and that as the pain grew less the swelling gradually diminished. For a few days before admission solid food seemed to increase the severity of the symptoms, and attacks of vomiting occurred, followed by some relief of the pain. He had had no diarrhœa or melæna at any time. On admission the patient was seen to be a thin, typically "strumous" boy; the thoracic organs proved to be healthy. No enlarged glands were present. On examining the abdomen a slight prominence was visible in the right hypochondriac region just beneath the outer margin of the rectus muscle, and moving with the diaphragm on respiration. This swelling was found to be caused by an ill-defined mass of about the size of a hen's egg, deep but not apparently attached to the abdominal walls; it was slightly moveable, and also moved with respiration; it was dull on percussion, and on palpation it was found to be irregular in outline and soft; no fluctuation could be detected. The dulness was continuous with that of the liver and the position of the swelling corresponded very closely with that of the gall-bladder. There was no general distension of the abdomen and no tenderness over McBurney's point. The urine was normal. After admission it was found that there was no rise of temperature even at night. For the first two or three days the patient was fed on milk and beef-tea only, and at once the attacks of pain became less severe, though the physical signs did not alter. The bowels were kept regular by doses of castor-oil and there was nothing abnormal in the motions. On Feb. 28th some solid food was given, and in the evening he had a severe attack of pain and vomiting, and then it was noticed that the swelling had moved more to the left side of the middle line, and that the right side of the abdomen was distended and tympanitic. The swelling itself also was not so dull on percussion. Gradually, as the pain and vomiting diminished, the swelling returned to its former position and the abdominal distension disappeared. During the following week the symptoms remained much the same, but some blood and mucus appeared in the motions. No change having taken place in the physical signs it was decided to perform an exploratory laparotomy. Accordingly on March 18th the patient was anæsthetised with the A.C.E. mixture, and Mr. Barrow made an incision about four inches long in the middle line above the umbilicus. This incision was deepened, and when the peritoneal cavity was opened a mass immediately presented itself. With some difficulty this mass was brought out of the opening and examined; it proved to be an intussusception occurring at the ileo-cœcal valve. It was about five inches in length and was surrounded by a mass of inflammatory adhesions; amongst these was found the vermiform appendix, which was easily freed. Mr. Barrow then attempted to withdraw the intussuscepted bowel; but finding that this was impossible he decided to remove the whole of the affected portion of the intestine, so the ileum as it entered the mass and the colon as it left it were isolated and clamped three inches or so from the intussusception. During this manipulation it was noticed that many of the mesenteric glands were enlarged, apparently from tuberculous disease. The bowel was then divided above and below, the peritoneal cavity being shut off by sponges, and the mesentery having been ligatured to control the hæmorrhage, the mass was removed. The ends of the bowel were then brought together and united by means of a Murphy's button; but when the button was closed it was found that a portion of the mucous membrane was projecting. This was cut off close to the button with scissors, and a few catgut sutures were put in to cover in the free edge. The bowel was then replaced in the abdominal cavity and the wound completely closed. For the first four days after the operation the patient complained of a good deal of abdominal pain, and a considerable quantity of mucus was passed per rectum, but there was no vomiting or distension of the abdomen. The temperature remained almost normal, only once reaching 100° F. On March 29th the stitches were removed, as the wound had completely healed. The patient was apparently well. On April 10th (twenty-three days after the operation) the button was passed with a motion. For five weeks he was fed on liquid food, and after this he was allowed light, solid food. No fresh symptoms appeared, and he was discharged quite well seven weeks after the operation.

The specimen after removal was found to consist of a portion of the ileum intussuscepted into the cæcum. At the apex of the intussusception there was a large tuberculous ulcer surrounded by much swelling; a second circular ulcer was found a little higher up. The peritoneal surfaces of the included portions of bowel were firmly adherent. There was apparently no obstruction, as the finger could be easily passed through the narrowed apex of the intussuscepted bowel. The symptoms of obstruction (vomiting and distension) were apparently due to impaction of fæcal matter above the stricture.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.

A CASE OF REMOVAL OF A LARGE SACRAL TUMOUR IN AN INFANT TWO HOURS OLD; RECOVERY; HISTOLOGICAL EXAMINATION.

(Under the care of Mr. C. E. RUSSEL RENDLE.)

CONGENITAL sacral and coccygeal tumours are by no means common, and are of great interest from an embryological point of view. They were first fully described by W. Braune in 1862.[1] Similar cases were described subsequently

[1] Die Doppelbildungen und angeboren geschwülste der Kreuzbe'ngegend, p. 52.

Hosted by Google

by Ahlfeld,[2] von Bergmann,[3] and many others, but the correct explanation of this variety of tumour was given by K. Middeldorpf,[4] who showed that they are due to a persistence of the post-anal gut. The tumour in section resembles more or less the thyroid gland, and so it has been given, somewhat unfortunately, the misleading name of "thyroid dermoid." Another feature of interest in the following case is the very early age—namely, two hours—at which the operation for the removal of the tumour was performed. As a rule, infants only a few hours or days old do not stand operation well; their tissues are very lacerable, and an amount of hæmorrhage which in anyone else would be of no importance is sufficient to cause a dangerous degree of collapse.

On April 11th, 1896, while the late Mr. W. Square and Mr. C. E. R. Rendle were operating at the South Devon and East Cornwall Hospital, a female child two hours old was brought in by a practitioner in the town as she had a large tumour growing in the region of the anus; it had not, he stated, interfered with labour, the child being born naturally, without the aid of instruments. On examination there was found to be a large, semi-solid swelling attached to the coccygeal region by a broad base, apparently of loose connective tissue; the anus was a good deal pulled upon, but was not occluded, and the other parts seemed normal. It was decided to remove it at once. Chloroform was given, and, the skin being divided all round the base of the tumour, a very little dissection with the handle of the scalpel sufficed to separate the attachments, which were nowhere firm, save that a thin fibrous cord appeared to run from the coccyx into the growth. The wound was sutured with horsehair, and despite considerable difficulty in maintaining asepsis, owing to its situation, it healed practically by first intention, the child thriving well. She weighed just 6 lb. ten days after the operation. The tumour itself weighed 26 oz. immediately after removal, and was seven inches long by five inches across. The child recovered perfectly from the operation, and appeared likely to grow up quite healthy. Six months after the operation the scar had markedly shrunk, and she had never had any bowel trouble. Unfortunately in January, 1897, while suffering from whooping-cough, she succumbed to an intercurrent attack of bronchitis. The case seemed worthy of record from the comparative infrequency of these thyroid-dermoid tumours, and the very tender age of the patient.

Histological examination.—Dr. H. W. Webber kindly undertook the histological examination of the tumour. He reported that it was composed of numerous cysts, varying in size from a Tangerine orange to a pin's head, the amount of solid inter-cystic substance being very small. The smaller cysts contained a glairy fluid, which showed under the microscope red blood corpuscles in varying proportions, granular débris, and developing epithelium; the larger ones contained a similar fluid, with some blood-clots, their walls being composed of fibro-areolar tissue (the spaces of which were densely packed with large nucleated cells, which could hardly be differentiated from those in the inter-cystic substance) and lined with columnar epithelium. In the larger cysts were also found nodules of cartilage, and two irregular masses of bone, one as big as a small hazelnut. It was evidently one of the thyroid-dermoid tumours described by Mr. Bland Sutton.

FREEMASONRY.—*Rahere Lodge, No. 2546.*—A regular meeting of this lodge was held at Frascati's Restaurant on May 11th, Brother Alfred Cooper, W.M., F.R.C.S. Eng., being in the chair. Brother Worthington was raised to the third degree. Messrs. Sargant, Haines, Bill, Ellis, and Christopherson were elected members of the lodge, and Messrs. Sargant, Haines, and Bill being in attendance were duly initiated into Freemasonry. Brother W. J. Walsham, F.R.C.S. Eng., was duly elected Worshipful Master for the ensuing year. Brother W. Gripper, M.B. Cantab., M.R.C.S. Eng., was elected treasurer, and Brother Madden tyler. Messrs. Matthews and Miles were proposed as members. A donation was voted in aid of the restoration of St. Saviour's Church, Southwark. Sixty members and their friends subsequently dined together.—*Raymond Thrupp Lodge.*—On May 5th Bro. Francis Taylor Simson, L.R.C.P. Lond., L.S.A., was duly installed Worshipful Master.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Teratoma of the Scalp.—Trophic Affections of the Joints.—Impacted Gall-stone.—Acromegaly.—Card Specimens.—Election of Officers.

A MEETING of this society was held on May 18th, the President, Mr. BUTLIN, being in the chair.

Dr. DOUGLAS DREW exhibited a specimen of Teratoma of the Scalp removed from the head of a man, thirty-six years of age, who had noticed it for seven years and thought that during that time it had slowly increased in size. It formed a hard nodular mass over the upper and posterior part of the right parietal region, the skin being thinned over it. When an incision was made it shelled out readily, and was found to be superficial to the tendon of the occipito-frontalis muscle. The tumour measured about one and a quarter inches in its longest diameter, its surface was somewhat nodular, and on section it appeared to be composed of cartilage, with a small amount of bone forming incomplete septa. A microscopical examination after the specimen had been decalcified showed the main mass of the growth to be cartilaginous, with some foci of ossification. But in addition to this a great diversity of elementary tissues was present. At one part there was a glandular structure, the spaces of which contained columnar and spheroidal epithelium, at another there were bands of fibrous tissue embracing lobules of fat, and also enclosing spaces lined by cells closely resembling stratified squamous epithelium, the interior of the spaces being filled with granular material.

Mr. TARGETT read a paper on the so-called Trophic Foot, which was illustrated by numerous specimens, drawings, and lantern slides. After indicating the main anatomical features of Charcot's joint disease in its different forms, two preparations were described in which the ankle-joint was chiefly affected, the lesions exhibited being those of the hypertrophic form of osteo-arthropathy, with great deformity produced by displacement of the foot. The second series of specimens illustrated absorption of parts of the tarsus and metatarsus, ankylosis of the remaining fragments and joints, and dorsal displacement of the metatarsus upon the row of cuneiform bones. In these instances there was complete absence of the usual signs of past suppuration or ulceration, and it seemed fair to assume that the destruction of bones and joints was not the result of septic infection. In the third class of cases it was impossible to eliminate the influence of septic infection, for in each instance the foot had been infected with one or more perforating ulcers of long standing. Some of these ulcers communicated directly with the carious bones; in others, the medium of infection was less obvious; but in all of them the foot presented the clinical signs of chronic hard œdema and cellulitis with varying degrees of deformity depending on the loss of bone and displacement of parts. A precisely similar condition of foot associated with trophic ulcers was shown from a case of well-marked syringomyelia. Hence the lesions described by Professor Charcot as characteristic of the "tabetic foot" occurred also in syringomyelia, and perhaps in other rare conditions; therefore, the more comprehensive term "trophic foot" had been adopted. Among the rarer conditions were mentioned arthropathy, due to peripheral neuritis, and that following severe woundsof the nerves. Lastly, it was pointed out that the remarkable deformities of the foot in Friedreich's disease, and in certain cases of ataxy (Joffroy's deformity), were due to entirely different causes, and must not be included among the various forms of "trophic foot."

Dr. NORMAN MOORE showed a Gall-stone which was found impacted in the Small Intestine, about fourteen feet away from the ileo-cæcal valve. The patient was a man, fifty years of age, who was suddenly seized with abdominal pain and vomiting on May 7th last. The next day he had stercoraceous vomiting, and three days later he was admitted into St. Bartholomew's Hospital in an almost moribund condition, and died before surgical exploration could be carried out. At the necropsy the stone was found to be firmly impacted in the position mentioned. The bile-duct was dilated and ulcerated, but there was no perforation and no peritonitis. Dr. Moore referred to similar cases which had been recorded by Mr. Bryant and by Dr. Gray of

Hosted by Google

Oxford. All three cases had a sudden onset, and vomiting, at first bilious and afterwards fæcal, had been persistent.

Dr. NORMAN DALTON showed recent specimens from a case of Acromegaly. The patient was a man, twenty-three years of age, who was quite well till 1893, when he had an attack of typhoid fever, after which his feet and hands began to increase in size, his features became coarse, and he became rather stupid. In addition he developed symptoms of diabetes, and it was for this complaint that he was admitted to hospital. When admitted he showed the characteristic symptoms of acromegaly, except that there was no great enlargement of the lower jaw. He died soon after admission from diabetic coma. At the necropsy, in addition to the external signs of acromegaly, there was found to be a general enlargement of the viscera, without in most cases any naked-eye alteration of structure. Thus the liver weighed 90 oz., the spleen 9¾ oz., the heart 13 oz., and the kidneys weighed 9 oz., but in their case there was probably some nephritis. The pancreas was very large, elongated, and soft, the thyroid was moderately enlarged, the thymus was very large, and the pituitary was enlarged so much as to distend the sella Turcica, and contained several drops of a fluid resembling pus. It did not appear to have compressed the commissure, and there was no optic atrophy. The suprarenal bodies appeared to be quite normal. There were signs of inflammation along the whole course of the alimentary canal, there being follicular tonsillitis, and the mucous membrane throughout was congested, and the lymphoid follicles were much swollen. The lymphatic glands in the neighbourhood of the fauces and also the mesenteric glands were much enlarged, but there was no enlargement of the glands in the axillæ and groins. There was some pigmentation over the fibrous nodules in the abdominal walls, and the skin in the axillæ was thrown into folds, thickened, and pigmented. In addition to the changes in the skeleton that could be observed during life, there were some spines of bone projecting from the basilar process, and there was a boss projecting from the middle fossa which indented the brain. With this exception the brain appeared healthy. Dr. Dalton referred to a similar case recorded by a Brussels physician, in which diabetes, ending in diabetic coma, and general enlargement of the viscera were associated with acromegaly in a man forty years of age. He hoped to report on the present case in more detail when a careful microscopic investigation had been made.—Dr. H. D. ROLLESTON remarked on the occurrence of pigmentation, although the suprarenal bodies appeared to be normal, and suggested that it might be due to an abnormal condition of the thyroid gland, and that the pigmentation was of the same kind as that met with in some cases of exophthalmic goitre. There was much evidence that the thyroid was partly responsible for the symptoms of acromegaly. The disease had been known to occur after goitre and exophthalmic goitre, and it had been benefited in others by thyroid treatment.

The following card specimens were exhibited:—

Dr. ALLCHIN: Ulcerative Colitis.

Dr. HERR: (1) Tuberculosis of the Tongue; (2) Hydronephrosis; and (3) Cirrhosis of the Liver in Congenital Syphilis.

Mr. A. H. TUBBY: Fracture-dislocation of the Cervical Vertebra.

The annual general meeting was then held. The report showed that there was some falling off in the admissions of new members. The balance at the bank showed a great shrinkage, but this was accounted for by the extra expenditure incurred by the Jubilee meeting of the society at the beginning of the session and by the purchase of microscopes by the society to avoid the heavy expense hitherto incurred in hiring them. The usual votes of thanks were passed to the retiring officers, and the following gentlemen were appointed to hold office in the next session:—President: Dr. Joseph Frank Payne. Vice-Presidents: Dr. Radcliffe Crocker, Dr. William Richard Gowers, Dr. Frederick Taylor, Dr. Samuel West, Mr. Arthur E. J. Barker, Mr. Stanley Boyd, Mr. Robert William Parker, and Mr. Samuel G. Shattock. Treasurer: Dr. Sidney Coupland. Honorary secretaries: Dr. Richard G. Hebb and Mr. D'Arcy Power. Council: Dr. John Abercrombie, Dr. J. Rose Bradford, Dr. Julius Dreschfeld, Dr. William Hunter, Dr. Hector Mackenzie, Dr. Hubert Montague Murray, Dr. G. Newton Pitt, Dr. F. Charlewood Turner, Dr. A. F. Voelcker, Dr. J. W. Washbourn, Mr. James Berry, Mr. Anthony Bowlby, Mr. Raymond Johnson, Dr. H. A. Lediard, Mr. John R. Lunn, Mr. Bilton Pollard, Mr. H. Betham Robinson, Mr. W. G. Spencer, Mr. J. H. Targett, and Mr. Edgar W. Willett.

CLINICAL SOCIETY OF LONDON.

Chronic Hydrocephalus.—Wound of the Mesentery.—Strangulated Hernia.—Femoral Hernia.

A MEETING of this society was held on May 14th, the President, Dr. BUZZARD, being in the chair.

Dr. FREDERICK TAYLOR read a paper on a case of Chronic Hydrocephalus, which was fatal at the age of sixteen years. The boy was admitted into Guy's Hospital with acute cerebral symptoms on Sept. 11th, 1895. He had had a large head from early infancy. At the age of eight months he suffered from bronchitis and had a number of fits, but he afterwards grew up strong and well, went to school, and at twelve years of age learned to play the violin. At the age of thirteen and a half years he became a compositor, and continued in that employment until his last illness, which commenced on Sept. 2nd with headache and vomiting. On the 6th he became giddy, vomiting was frequent, and there was constant severe headache, so that he gave up work. On the 11th, when he first came to to the hospital, the principal symptoms were constant headache—chiefly frontal, but sometimes occipital—vomiting, and unsteady gait. The head measured 23 inches in circumference. A few days later his head was retracted, and the vomiting and headache persisted. On the 19th there was loss of power in the legs, and pain was felt in the back of the neck. On the next day the paralysis extended, there was weakness of the arms and to a less extent of the face, and the diaphragm became paralysed. He died on the same day, with increasing embarrassment of respiration, but with preservation of consciousness to within three hours of his death. The necropsy showed that the bones of the skull were much thinned. The cerebral hemispheres were much distended, the ventricles containing thirty ounces of fluid. The pia mater was thickened at the base of the cerebellum, especially near the foramen of Majendie, but it was not certain that this was occluded. There were firm adhesions at the margin of the foramen magnum. Dr. Taylor called attention to the rarity of hydrocephalus existing till the age of sixteen years without impairment of the intellectual faculties or other symptoms. The short terminal illness of three weeks' duration could only be explained by a spontaneous increase in the quantity of fluid.—The PRESIDENT said that the retention of mental powers was very remarkable. He noticed that Dr. Taylor described an atrophic condition of the thenar muscles. Was this regarded as a sign of involvement of the spinal centres or was it part of the general atrophy?—Dr. TAYLOR, in reply, said that there was not much general emaciation. He imagined that the symptom indicated spinal involvement, but, unfortunately, he was not present at the necropsy and the spinal cord was not examined.

Mr. C. B. LOCKWOOD related a case of Wound of the Mesentery with subsequent Gangrene of the Intestine. The patient was a man, aged sixty-four, who had endeavoured to commit suicide by stabbing himself in the left side of the abdomen with a carving knife. He was found unconscious lying in a pool of blood, with coils of intestine protruding from the wound. As soon as he had partially recovered from the shock the abdomen was opened to stop the hæmorrhage. It was found that the bleeding came from several rents in the mesentery. The bleeding points were secured and the rents closed. Most of these were parallel to the large vessels; but one, three-quarters of an inch long, was parallel to the bowel and only half an inch from it. This was sewn like the others, and it was hoped that there was room for anastomosis in the mesentery between the wound and the bowel; but when the man died two days afterwards the bowel opposite the wound was either dead or on the point of dying. Mr. Lockwood had since carefully examined the vascular supply of the mesentery and bowel in the dissecting-room, and no anastomotic loops were found less than half an inch from the bowel. He had no doubt now that the proper plan would have been to have resected the intestine.—Mr. SPENCER said that the statements in anatomical books about the free anastomosis in the mesentery were erroneous as shown by Litten and illustrated by Mr. Lockwood's case. He thought that possibly the branch ligatured by Mr. Lockwood was a larger one than he had imagined at the time.—Mr.

Hosted by Google

HOWARD MARSH related a case of a man who was thrown from his horse while hunting, and fell on a heap of stones. There were no symptoms for the next twenty-nine hours, and the patient went into the City on business the next day. He then rather suddenly became collapsed. The abdomen was explored, and several feet of the intestine were found to be in a condition of gangrene. At the necropsy a large rent was found in the mesentery, which had severed a large branch of the superior mesenteric artery, from which, however, not much hæmorrhage had occurred. The latency of symptoms was very remarkable.—Mr. MCADAM ECCLES asked what was the explanation why the other rents had not caused gangrene. Was it possible that this part had protruded from the wound during the operation, and had been nipped by the contraction of the rectus.—Dr. FREDERICK TAYLOR mentioned the case of a child who was taken suddenly ill with symptoms of peritonitis. At the necropsy there was a good deal of blood in the peritoneal cavity, and a foot of the intestine was gangrenous and full of blood. The cause was apparently thrombosis of a large branch of the superior mesenteric artery, which was calcareous. A previous case of the kind had been recorded by Fagge.—Mr. LOCKWOOD, in reply, said that it was obvious that the gangrene corresponded to the slit that he had described, the large vessel, which had been suggested by Mr. Spencer as responsible, was some distance away. The cases mentioned by Mr. Marsh and Dr. Taylor showed that anastomosis was not to be relied on.

Mr. HOWARD MARSH related a case of Strangulated Hernia in which he had been obliged to incise the intestine freely in order to return the bowel, with a good result. A man, thirty-eight years of age, who had had a reducible hernia for some years found on getting up one morning that he could not return it. Twelve hours later he was admitted into St. Bartholomew's Hospital. The symptoms were severe and he was becoming collapsed. On opening the sac it was found that there was no fluid in its cavity, but that the contained coils of the small intestine were so distended that there seemed danger that they would burst. They were at once freely incised in three places, and were found to contain about a pint of blood-stained fluid. The incisions were closed by Lembert's sutures and the coils returned, the patient recovering without any drawback. He (Mr. Marsh) suggested that the practical explanation was that the peritoneal coat of the gut had by paralytic distension of the coils been so firmly pressed against the interior of the sac that exudation from the serous surface had been prevented, and that it had thus occurred from the mucus membrane, so as to collect in the canal of the intestine.—Mr. LANGTON did not think that effusion of blood and mucus was so very rare. Sometimes the constriction was entirely external, the mucous membrane being last involved, and in these cases effusion took place into the sac. In other cases the process was more complicated, and swelling first took place in the mucous membrane, there being often an antecedent enteritis, and the peritoneum was last affected. In these cases the intestine became distended with fluid, and he had several times adopted the procedure described by Mr. Marsh, and incised the sac, evacuating it and then returning the bowel.—Mr. LOCKWOOD asked what part of the intestine was involved. He had seen much blood effused into the lumen of the intestine in a strangulated umbilical hernia. In that case the jejunum, the thickest and most vascular part of the bowel, was affected.—Mr. SPENCER suggested that the fluid in Mr. Marsh's case was a "paralytic secretion," similar to that obtained experimentally by isolating a loop of intestine, and dividing its nerves of supply.—Mr. EASTES inquired if there was any previous enteritis in this case.—Mr. MARSH, in reply, said that he quite agreed with Mr. Spencer's view that the fluid was a paralytic exudation.

Mr. L. A. BIDWELL read a paper on two cases of Femoral Hernia in which the vermiform appendix alone was found in the sac. Both the cases occurred in females, and the hernia, though irreducible, had given rise to no symptoms of strangulation. In both his cases he had reduced the vermiform appendix after notching Gimbernat's ligament, and he recommended this treatment instead of excision in all cases where the appendix was not diseased. Very few cases of this condition had been recorded, but in most of them the appendix had been excised.—Mr. LANGTON mentioned the case of a woman, forty-six years of age, in whom he found a similar condition and remarked that the symptoms of strangulation were seldom marked in these cases, which were not rare in the inguinal region, practically always on the right side, but which were very rare in the femoral region. If the appendix was not ulcerated or adherent it might be returned, but if it were altered it any way it should be excised. In order to return the hernia he should incise the sac freely, but he would prefer to notch Hey's ligament rather than Gimbernat's, as causing less subsequent weakness of the abdominal wall.—Mr. MCADAM ECCLES referred to a case which he showed last year at the Pathological Society in which an appendix was found in a femoral hernia. The vermiform process in this case was unusually long, and he thought that it had been fixed at the extremity and that stretching had occurred. He suggested that some of the supposed cases of strangulation were cases of appendicitis within the femoral sac. The appendix had a great tendency to become adherent, and it was often easier to remove it than to separate the adhesions. The existence of an appendix in a hernia was one of the causes of hydrocele of the sac.

HARVEIAN SOCIETY OF LONDON.

Some Resources in the Diagnosis of Nervous Diseases.

A MEETING of this society was held on May 13th, the President, Dr. R. H. MILSON, being in the chair.

Dr. CAGNEY read a paper on Some Resources in the Diagnosis of Nervous Diseases, illustrating it by a series of clinical cases of peripheral nervous disorders. These he investigated before the society and took occasion to demonstrate practically the use of electric currents in diagnosis. He dwelt upon the importance of this one element of certainty amongst what is so often complex and ambiguous, and defined the limits within which the result obtained by noting the electrical reactions of muscles was absolutely to be depended upon. Amongst the cases which he exhibited was a middle-aged woman, the subject of alcoholic neuritis, showing at the same time general muscular tenderness with total analgesia of the skin all over the body, this and other symptoms being obviously hysterical; and he also related the history of other cases within his experience, urging the necessity of a departure from the usual mental attitude, by which it was assumed that if a patient was hysterical therefore he was not the subject of organic disease, the fact being in his opinion that the unstable nervous system of the hysterical was more likely than another to suffer from coarser lesions. The discrimination of the two elements, the functional and the organic, occurring in the same person seemed to him to be a task of the first importance—a task which could not be satisfactorily performed without a knowledge of the electrical reactions. *Apropos* of certain cases of anterior poliomyelitis, he called attention to clinical appearances tending to modify the usual conception regarding the pathology of these affections.

Mr. GRIFFITH desired to know if electricity could be utilised in the diagnosis of ocular paralysis and so assist the prognosis of such cases. He had met with a number of cases in which the cause had been obscure, and though many had yielded to iodide of potassium, others had been most obstinate to treatment.

Dr. CAGNEY, in reply, said that the ocular muscles were not amenable to the ordinary method of examination.

ÆSCULAPIAN SOCIETY OF LONDON.

Cancer of the Rectum.—Exhibition of Cases.

A MEETING of this Society was held on May 7th, 1897, the President, Mr. STEPHEN PAGET, being in the chair.

Mr. D. H. GOODSALL read notes of six cases of Cancer of the Rectum. A family history of cancer was discovered in one case only. The patients came under treatment at periods varying from three to eighteen months after the onset of symptoms suggesting rectal mischief. The tumour mass could be felt in most of the cases from two to three inches above the anus, but in one instance it was placed as high as five inches. Left inguinal colotomy was performed in four of the cases. The rectal growth was removed in three cases. In one case the latter operation alone was done, the coccyx also being taken away, and a preliminary colotomy was not resorted to. The results in all the cases had so far been satisfactory. The ages in these cases gave an average of fifty-nine years for the males and of sixty-six years for the females. The

Hosted by Google

previous health had as a rule been good, the only ailment being constipation. Mr. Goodsall observed that men were on the whole more liable to cancer of the rectum than women. The usual progression of symptoms was diarrhœa—first without, but afterwards with, blood; later, a lack of control over flatus, and pain over the sacrum and coccyx and sometimes in the penis; and after six to nine months loss of weight. He insisted on the necessity of a rectal examination in any case of persistent and unexplained diarrhœa. Sometimes, however, obstruction was an early symptom. As to treatment he advocated free removal of the growth, care being taken to excise freely the skin towards the front of the wound where a recurrence was usually noticed. If this operation were refused left inguinal colotomy should be done and would arrest the diarrhœa, discharge of blood and mucus, and tenesmus.

Mr. GOODSALL also showed:—1. A case of Fistula in Ano following Rectal Stricture. Sinuses had burrowed towards the scrotum and even for several inches along the thigh. These having been opened up the patient had become convalescent. 2. A case of Early Epithelioma of the Tongue.

Dr. CONNER showed a case of Extensive Morphœa in a girl aged thirteen years. Characteristic pale patches of various sizes were scattered over the arms, legs, abdomen, and shoulders. Some were slightly indurated.

Mr. M'DONNELL showed a case of Mitral Stenosis in the initial stage. No rheumatic or other constitutional cause was discoverable.

POOR-LAW MEDICAL OFFICERS ASSOCIATION.

Poor-law Officers Superannuation Act.

AT a meeting of the Council, held at 9, Copthall-avenue, E.C., on May 11th, Mr. W. D. BALDING being in the chair, Messrs. Beckingsale, the solicitors to the association, reported that, in answer to the questions propounded to Sir Robert Reid, Q.C., M.P., *re* the Poor-law Officers Superannuation Act, 1896—viz., (1) Are public vaccinators officers under this Act, and, as such, entitled to superannuation under the Act of 1896? (2) Has the Local Government Board sole power to decide whether public vaccinators are officers or not? (3) If public vaccinators are officers, are they entitled to superannuation under the Act? (4) Whether medical officers who are entitled under the Act to superannuation as such are also entitled to a further allowance in respect of the office of public vaccinator where they hold such an appointment?—they had received the following reply:—

1, Temple-gardens, E.C., May 7th, 1897.

1. Reading the different portions of the Poor-law Officers Superannuation Act together, the only persons [except those specially mentioned in the definition clause] entitled to superannuation are persons between whom and the guardians there is a relation of service or employment. The Act does not confer superannuation upon persons whose relation to the guardians is that they merely contract with them to do specified work.

In the case of district medical officers they are, according to the term of the statutes, "appointed" to an "office," and paid a salary. So they are "officers" employed by the guardians.

Now the position of public vaccinators is required by 30 and 31 Vict., c. 84, under which the guardians do not "appoint," nor is the position called therein an "office" nor is a salary paid. The guardians are required to enter into a contract with some duly registered medical practitioner, called the public vaccinator, which is to contain stipulations and conditions to secure the due vaccination of persons, &c.

We do not consider that this statute creates a relation of service or employment, nor is such relation created by the terms of the contract itself set out in Glen's Poor-law Orders, p. 525, though it might be. And we assume that the contract is always in those terms.

We think, therefore, there is no title to superannuation on such a contract. It is true that superintendent registrars and registrars of births and deaths are, by Section 19 of the Act of 1896, deemed to be in the service of the guardians. The reason is that by the Acts creating their officers they are not in the service of the guardians, though they are "officers," and so styled in the Acts.

This, therefore, does not effect the question here raised, and a similar reason exists for the mention of "school attendance officer" in Section 19.

2. The Local Government Board have no power to determine this question. They can only determine differences between the guardians and persons who in fact are officers.

3. This has been already answered.

4. Medical officers of the guardians who are entitled to superannuation under this Act are not entitled to a further allowance in respect of the office of public vaccinator, if they hold such, as Section 19 of the Act lays down that only those emoluments are to be included that accrue to the officer in virtue of the office for which he claims superannuation.

It was unanimously resolved that a copy of the above be sent to the medical press.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Solid Tumours of the Ovary.—Cystic Sarcoma of Muscle.—Intra-hepatic Thrombosis.—Intra-ocular Hydatid Cyst.—Exhibition of Specimens.

A MEETING of this society was held on May 12th, Dr. T. HARRIS, President, being in the chair.

Dr. DONALD showed some Solid Tumours of the Ovary removed by abdominal section. The specimens included: 1. A solid tumour about the size of a fœtal head, removed in 1893 from a child aged six years and one month. On microscopical evidence the growth was pronounced to be a spindle-celled sarcoma, but there had been no recurrence after operation. 2. Three cases of fibromata of the ovary, removed from patients aged twenty-six, thirty-nine, and fifty-two years respectively. In the third case the tumour weighed 19 lb. 3. A fibro-myxoma of the ovary. 4. A fibro-adenoma of the ovary. Microscopical sections of the various tumours were also exhibited.

Mr. E. STANMORE BISHOP showed a Cystic Sarcoma of the Semi-tendinous muscle. The whole muscle was converted into a fluid sac, and it was entirely removed. The patient recovered and could walk well. Sections of the wall of the growth, for which he was indebted to Dr. Kelynack, were shown. They exhibited a small spindle-celled structure with some myeloid cells.

Dr. FOX EDWARDS made some remarks on the Leucocytes in Leukæmia, and showed specimens of Blood from cases of Lymphatic and Myelo-splenic Leukæmia. The essential differences between the two varieties were pointed out: the increase in leucocytes in the lymphatic form affecting almost entirely the lymphocytes, but in the myelo splenic form affecting both varieties of oxyphile cells; and, in addition, in the latter form myelocytes were present. Specimens showed every stage between ordinary finely granular oxyphile cells and myelocytes with oxyphile granules, which fact led him to suggest that certain of the myelocytes might be abnormally developed and finely granular oxyphile cells.

Dr. KELYNACK showed a specimen from a case of Stenosis of the Hepatic Vein, with extensive thrombosis of its branches in the liver. The patient was a woman aged thirty-two years. The chief symptoms were enlargement of the liver, ascites, and jaundice. The illness lasted six weeks, death resulting apparently from cholæmia.

Dr. HILL GRIFFITH mentioned a case of Intra-ocular Hydatid Cyst and remarked on its extreme rarity.

The following Card Specimens were exhibited:—

Dr. BRINDLEY: Biliary Cirrhosis.

Dr. MOORE: Microscopic Preparations from "Alcoholic Heart."

Dr. WOODCOCK: Foreign Body from the Pharynx.

Mr. WOLSTENHOLME: (1) Lung from a case of Glanders in a Horse; and (2) Cultures of Bacillus Mallei.

Dr. YONGE: Singer's "Node" of the Vocal Chord.

Dr. KELYNACK: Malignant Growth of the Heart.

Dr. MACNEILAGE: Anencephalic Fœtus.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Acute Nephritis.—Invaccinated Erysipelas.—Myxœdema.—Recurrent Appendicitis.—Transposition of the Viscera.

A MEETING of this society was held on May 4th, the President, Mr. GODFREY CARTER, being in the chair.

Dr. WEBB related a case of Acute Nephritis complicating Pregnancy. The patient was a woman, eighteen years of age; she was five months pregnant when admitted to hospital on Sept. 4th, 1896, and had enjoyed good health until three months previously, when she noticed that her legs were swollen. On admission all the signs of acute nephritis were present, the urine was smoky, loaded with albumin, and the quantity 21 oz. No change was present in the fundus oculi. The patient was dull and drowsy and complained of headache. Her condition improved till Oct. 17th, when she had a convulsion and her breathing became stertorous. Venesection was performed, 12 oz. of blood being withdrawn, and one and a half pints of normal saline solution were then transfused; after this the patient seemed much better. A sound was introduced into the uterus and passed round

Hosted by Google

between the membranes and the uterine walls, and a catheter was then passed into the uterus and left in. On Oct. 23rd the patient was delivered of a living child, which survived twenty-four hours. On Nov. 18th the patient complained of dimness of vision, and on examination optic neuritis, together with old and recent hæmorrhages into the retina, were seen. On Feb. 13th she was sent home apparently in a convalescent state, but several convulsions occurred, and next day she was re-admitted in a semi-comatose state, her pulse being 76 and weak. She had passed urine, but the bowels had not acted. A simple enema was administered, and after this a pint of saline solution was introduced into the rectum through a long tube; part of this was retained. She was wrapped in a blanket wrung out of hot water and perspired freely. On Feb. 16th her condition was rather better; she had no more convulsions, but was still semi-conscious; her urine was loaded with albumin. On Feb. 20th she was much better, the albumin was greatly diminished in amount, and the optic discs were natural. On March 6th she left the hospital in a very satisfactory condition, with only a trace of albumin in the urine, and three weeks later she was found to be still in good health.

Dr. BELL related a group of cases of Invaccinated Erysipelas. He pointed out that if the disease is inoculated at the time of vaccination the erysipelas will show itself about the fourth day. Nine children were vaccinated from an apparently healthy child. Cases 1, 2, and 3 ran a normal course. Cases 4, 5, and 7 developed erysipelas of the arm in the first week, but the vaccination pocks ran a normal course. Case 6 had an axillary abscess, and the development of the pocks was more rapid than natural. In Cases 8 and 9 the pocks developed more rapidly than natural, but there was no other inflammation. The vaccinifer in these cases was apparently normal at the end of the second week; at the end of the third week there was enlargement of the axillary glands, which subsided without suppuration.

Mr. MIALL related a case of Myxœdema in which treatment by thyroid gland and extract was followed by complete relief of all the symptoms.

Mr. HORROCKS related a case of Recurrent Appendicitis successfully treated by abdominal section and removal of the Vermiform Appendix.

Dr. JASON WOOD showed a patient with Transposition of the Viscera.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Renal Tumour.—Congenital Hypertrophy and Stenosis of the Pylorus.—Removal of a Fragment of Steel from the Vitreous Humour.—Intestinal Obstruction.—Catgut and Silk Rolled in Balls.

THE first meeting of the summer session of this society was held on May 5th, Dr. WILLIAM CRAIG, Vice-President, being in the chair.

Mr. F. M. CAIRD read a paper on a case of Renal Tumour. The patient was a man, aged fifty-six years, who had come under his care early in March complaining of hæmaturia, general weakness, and loss of weight. He first noticed blood in his urine in October, 1895. The bleeding had become practically continuous, and after exertion clots were passed. There was no acute pain, but a general heaviness and dull pain, usually referred to the left lumbar region, but more recently to the right were experienced. On March 20th the patient was put under chloroform and the bladder examined with the cystoscope, when granular detritus was seen issuing from the left ureter, while the bladder itself was healthy. The usual incision was made from a point between the last rib and the erector spinæ, forward and parallel to the twelfth rib. A tumour was found as large as a man's head. The patient suffered severely from shock during the efforts made to enucleate the tumour, and it was impossible to define a pedicle, or pass a ligature over the mass. It then occurred to Mr. Caird that the mass might be eviscerated. The posterior border of the kidney was laid open, and the soft, pulpy contents were scooped out with the right hand, while the left compressed the position of the vessels and ureter. The upper end of the kidney could then be detached, and a pedicle was felt, which was divided and ligatured. The patient was apparently moribund, but he gradually rallied towards evening. No urine was passed until the second day. Beyond a copious discharge from the wound the future history was uneventful. He rapidly improved in colour and in strength, gained weight, and was on a couch twenty-one days after the operation.

Dr. JOHN THOMSON read a paper on Congenital Gastric Spasm (Congenital Hypertrophy and Stenosis of the Pylorus). He has already recorded two cases of this condition, and the present communication was based upon a third case which he had seen in April of last year. The patient was a female infant, twenty-seven days old, suffering from constant vomiting and somewhat emaciated, but otherwise healthy. On careful palpation a small hard moveable tumour could sometimes be felt in the epigastrium. At birth the infant appeared to be normal. The mother not having enough milk the child was fed artificially, but vomiting began almost at once and rapidly became worse. The child steadily became emaciated and died. The post-mortem examination showed the stomach to be enlarged and its wall to be thickened towards the pylorus, the thickening being due to an increase in the muscular coat. At the pylorus the muscle was much thickened and the orifice was contracted so that the stomach contents could not be squeezed through it. The hypertrophy was mainly in the inner circular layer. The sub-mucous connective tissue was also greatly increased in amount. In these cases there was usually a period of apparently perfect health until the vomiting commenced. The vomiting at first occurred at long intervals, these diminishing until it followed each ingestion of food. The duration of life varied from three weeks to a little over six months. As regarded treatment the possibility of surgical interference was referred to. It was argued that the condition was a congenital one, originating in utero, and that it was the result of a functional disorder of the nerves of the stomach and pylorus, leading to antagonistic action of their muscular arrangements. This antagonistic action, he thought, must be connected with the swallowing of large quantities of the liquor amnii during intra-uterine life.

Mr. W. G. SYM read notes of a case in which a Fragment of Steel was removed from the Vitreous Humour. There was a traumatic cataract in the eye in which the steel was lodged. The usual cataract operation was performed, and the fragment of steel was removed with an electro-magnet, the result being very satisfactory.

Dr. ALEXIS THOMSON showed a male patient upon whom he had operated for Strangulated Hernia. Some months after the operation the patient suffered from complete intestinal obstruction, with fæcal vomiting, his general condition being one of extreme gravity. Stricture had occurred at the site of the strangulation, the intestine being much distended above this point and collapsed below it. It was necessary to remove about a foot and a half of intestine in order to obtain a satisfactory anastomosis. Murphy's button was employed. The patient made an excellent recovery and the Murphy's button was passed in about a fortnight.

Mr. CATHCART showed an ingenious method which he had devised of rolling Catgut and Silk in Balls to obviate the use of spools. The balls were put into a bottle, the ends being taken up through a plug of antiseptic wool with which the mouth of the bottle was closed. The catgut or silk readily unrolled, and the smearing of the hands of the surgeon was avoided.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Dissemination of Micro-organisms from Sewer Air.—The Report of the Vaccination Commission.

A MEETING of this section was held on April 30th, Dr. J. M. REDMOND, President, being in the chair.

Professor CHARLES TICHBORNE read a paper on the Dissemination of Micro-organisms and on the Best Method of Destroying Germ Emanations from Sewer Gas. He remarked that sewer gas was stated, with considerable force of evidence, to be a fertile source of spreading enteric fever and allied diseases, and in spite of some recent researches, he was still of opinion that the weight of evidence almost proved this to be the fact. But there was something wanted to explain the theory. Even the smallest germs had a certain weight. This fact is shown by the absence of germs at high altitudes, as for instance on Mont Blanc, or in very still atmospheres, such as that in the vaults of

Hosted by Google

St. Michan's Church. He had demonstrated this as far back as 1870 in an afternoon lecture delivered at the Royal Dublin Society. The microbes of enteric fever, when carried in water or brought mechanically to a receptive surface, were capable of producing disease, and they were also capable of rising in sewer gas. Professor Frankland had shown that liquid sewage matter was not likely to be scattered into the air except by gas generated in it. He experimented with lithia—a non-volatile chemical substance, which was easily detected and might be said to represent micro-organisms. He found that no ordinary agitation of the sewer water would produce indications of lithia in the air, but directly gas began to be generated in the sewage by decomposition, the bursting of the gas bubbles carried lithia into the air. Professor Tichborne was of opinion that here lay the clue to the dissemination of microbes, but his views did not take exactly the direction which Professor Frankland indicated, for he conceived that they could be carried by a condensed vapour exactly represented by ordinary dew. At certain hours of the night, just as the rising vapour settled as dew in a valley, he explained that the temperature of the water-laden vapour of the sewer was lowered by being met with the layer of cold night air through the open traps, which determined a dew point in the sewers themselves. He had found from actual experiment that the temperature of the sewer water as it flowed from the large sewers was generally two or three degrees above the temperature of the night air. Each particle of dew became a "raft" which would carry microbes upon its surface, perhaps for miles, as long as the condition lasted, and as the sun's warmth dissipated the morning dew the "raft" disappeared, leaving the microbe suspended in the air. He therefore recommended that sewers should be disinfected with insoluble disinfectants, having a specific gravity of from 0 850 to 0·950, so that they would float on the surface of the sewer water. Carbolic acid and disinfectants which were heavier than water were perfectly useless, because the unaffected stream of sewage passes over their surface.—SIR CHARLES CAMERON said that he had been much startled by recent papers which appeared to show that the air from sewers in London, Aberdeen, and other places contained a very small number of micro-organisms, much smaller, indeed, than the air above the sewers. He was much interested in Professor Tichborne's statement that the bubbles of vapour came up containing the germs contained in the liquid. It has been proved that sea water on the calmest day carries up salt into the air derived from the placid evaporation of the sea water, and therefore he could not accept the theory that liquids were unable to disengage the pathogenic bacilli which happened to be present in them. He had made many experiments, which consisted in placing dejecta of typhoid patients in an open vessel, at a little distance from some milk in vessels, and covering the whole with glass; examination revealed swarms of bacilli in the milk. He concluded that during the fermentation of fæces containing the bacilli there was an actual evolution, and that they escaped in gases. Perhaps this accounted for the fact that perfectly fresh fæces were not infective, but that putrefaction was necessary for gases to be evolved and to carry the germs into the air.

The Secretary read Dr. ALFRED E. BOYD'S paper on the Report of the Vaccination Commission for 1896. It dealt with the history of small-pox and the history of inoculation and vaccination, and then with the Commission, its scope and its recommendations. The recognition of "honest objections" was described as a dangerous principle, for it would put a premium on the endeavours of busybodies to convert the ignorant to anti-vaccination principles.

THE FRENCH HOSPITAL.—The twenty-ninth annual dinner of the French Hospital and Dispensary was held on May 15th at the Hôtel Cecil, Baron de Courcel, the French Ambassador, presiding. There was a numerous company, including the Italian Ambassador, the Lord Mayor, and the Under-Sheriffs. Sympathetic references were made by various speakers to the lamentable loss of life occasioned by the fire at the charity bazaar in Paris. Subscriptions and donations amounting to about £2500 were announced by the honorary treasurer, including £25 from the French Ambassador, £10 10*s.* from the Lord Mayor, £50 from the Italian Government, £100 from the late Duc d'Aumale, £10 from the Duc d'Orleans, and £10 from the Duc de Chartres.

Rebiews and Notices of Books.

A System of Medicine, by Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D., LL.D., F.R.C.P., &c., Vol. II. London: Macmillan & Co. 1897. Price 25*s.*

WE gladly welcome the appearance of a second instalment of a work which must undoubtedly rank as a foremost treatise on the scientific medicine of to-day. It contains contributions from those whose qualifications for the task imposed on them are of the highest order, so that the reader can feel certain to find in its pages the most recent as well as the most valuable information that exists on these matters. It is indicative of the wide area embraced by British medicine that a large part of the volume deals with diseases of tropical climates, concerning which knowledge has so much advanced of recent years, although at the same time there are many lacunæ to be filled. As to the growth of knowledge upon the intimate nature of diseases, we need only to glance at the opening article upon Tuberculosis, by Dr. Sidney Martin, to realise how widely different is the standpoint from which we now regard this and other morbid processes from that obtaining less than twenty years ago. This is owing in great measure to the recognition of the part played in infective diseases by bacterial organisms, and it thus comes to pass that bacteriology occupies a prominent place in the volume. Dr. Martin's article is in the main devoted to the general facts of tuberculosis, especially as to its etiology and pathology, and he has succeeded well in presenting a clear and harmonious description of the characteristic manifestations of the disease, which in all its varied forms can be referred to the introduction into the body of the bacillus tuberculosis. Dr. P. S. Abraham, in his article on Leprosy, deprecates the use of the term "tubercular" to the most characteristic variety of elephantiasis, rightly preferring to call it "nodular." It is remarkable how much there is still to be learnt concerning this disease, especially in regard to its etiology, for although there can be no question as to the specific and pathogenic character of the bacillus lepræ, it is yet uncertain how this organism gains entrance into the body. Dr. T. D. Acland's article on Actinomycosis gives a faithful description of this remarkable affection, the recognition of which is of comparatively recent date. Its rarity in the human subject may possibly not be so great as we think owing to the diagnostic fallacies that may be encountered. The discovery of the pathognomonic and quite characteristic organism in the discharges is of course conclusive. Next in order in the volume are articles on diseases which are familiar enough to the English practitioner. That on Measles is written by Dr. Dawson Williams, who gives an excellent account of the typical course of the malady, followed by a sketch of the chief departures from that type. In speaking of its complications it is to be noted that the writer attributes the most dreaded of these—broncho-pneumonia—to a secondary infection; for, as he says, "the catarrh determined by the primary infection of measles appears to favour the growth of certain pathogenetic organisms, chief among which are the pneumococcus, the streptococcus pyogenes, and the staphylococcus pyogenes aureus." The number of complications described is considerable, the most interesting of which are those connected with the nervous system. It is instructive to note that the toxin of measles would seem to have more affinity for the central than for the peripheral nerve-tissues, the conditions which have been met with including hemiplegia attributable to encephalitis or meningitis, muscular atrophy, "ascending paralysis," and disseminated myelitis. However, such sequels are all very rare. The same author contributes

Hosted by Google

a brief article on Rubella, the diagnosis of which from scarlet fever and from measles is facilitated by an instructive table. Dr. F. Foord Caiger's article on Scarlet Fever is of an exhaustive character. He has adopted, too, a systematic method of treatment of the subject which is of material assistance to the reader. The analysis of the symptoms of the disease indicates a wide acquaintance with its features, and is obviously the summarised exposition of careful clinical observation. It is interesting to learn that Dr. Caiger has not, and that others have not, been able to confirm the observation of the late Dr. Mahomed that the albuminuria of scarlet fever is preceded by a stage of hæmoglobinuria. A section on aberrant cases is of practical value, and the remarks on diagnosis are clear and concise. The subject of the complications of scarlet fever is one which demands a wide experience for its adequate treatment, and we may therefore take it that the statements here made are authoritative. It is satisfactory to find from the statistics which Dr. Caiger gives that the incidence of complication is not, on the whole, very high, and it may be a surprise to some to learn that acute nephritis did not occur amongst the patients of the Stockwell Fever Hospital in the years 1892 and 1893 in more than 3·4 per cent. Rheumatism is more common—namely, 4·5 per cent. Dr. Caiger believes that "scarlatinal rheumatism" is akin to ordinary acute rheumatism, but notes the greater tendency for the inflamed joints to suppurate. As regards post-scarlatinal diphtheria, to which much attention is given, we are told that "there is nothing, either clinically or bacteriologically, to distinguish post-scarlatinal diphtheria from the independent disease except in respect to its high mortality." It is pointed out that it mainly occurs in hospitals and that its appearance seems to be related to local conditions of soil and ventilation, for often any exposure to infection is out of the question. In discussing the pathology of the disease the well-known investigations of Dr. Klein in the Hendon milk-epidemic are detailed, and the grounds stated by that observer for considering the streptococcus then discovered to be pathogenetically distinct from the streptococcus pyogenes, which it morphologically resembles. We gather that Dr. Caiger is himself inclined to limit the operation of this microbe to the secondary "septic" phenomena which accompany all well-marked cases. The section on treatment is satisfactory, but the reader will fail to find in it any reference, critical or other, to the eucalyptol inunctions which a short time since were in vogue in some quarters. The method could not fail to have been tried in a large fever hospital, so we may perhaps conclude that it was found wanting in the merits claimed for it. Dr. J. MacCombie writes on Chicken-pox, and the vastly more important subject of Small-pox, upon which he has produced a most able essay. The recent epidemic wave that has been passing over this country has awakened an interest in this disease which to some of our Continental *confrères* is becoming as little known as typhus fever is to the majority of English medical men. An especially valuable part of an article which is throughout most exact and detailed is the consideration devoted to the subject of diagnosis. Here Dr. MacCombie has been careful to enter fully into a description of the numerous conditions liable to be mistaken for small-pox in its initial as well as in its developed stages. For whereas in its natural features variola is unmistakeable, in its modified form, it may readily pass unrecognised, so that it is not surprising that the earliest cases in an outbreak are mostly to be found amongst the vaccinated. In view of the importance of prompt isolation of the infected the necessity for accurate diagnosis is obvious. Dr. Eustace Smith writes on Mumps and Whooping-cough, subjects upon which his long experience of the maladies of children entitles him to speak with authority, and everyone will be glad to peruse the article on Constitutional Syphilis contributed by Mr. Jonathan Hutchinson. To Dr. Caiger has been assigned the treatment of a highly interesting subject—namely, that of the Co-existence of Infectious Diseases. He relates the following singular experience:—"A child once came under my care in whom scarlet fever, diphtheria, measles, and whooping-cough were all present at the same time, the only disease amongst them in which the diagnosis was doubtful being diphtheria, for the bacteriological test was not applied. In another case the eruptions of measles and chicken-pox were mingled with the early desquamation of scarlet fever in a child who at the time was suffering from whooping-cough. In both cases the combined attack was fatal."

The next division of the volume is devoted almost entirely to the description of tropical diseases, and is introduced by an article by Sir Joseph Fayrer on the Climate and Some of the Fevers of India. Amongst the latter he describes the various forms of malarial fever, and devotes several pages to the consideration of Indian enteric fever, the etiology of which is held by those who have had most experience of it to be dissimilar from the disease with which we are so familiar in temperate climates. For our own part we find much difficulty in harmonising our present knowledge of the specificity of the lesions of enteric fever with the statements as to the conditions under which that disease prevails in the tropics. Is it possible or conceivable that more than one pathogenic agent can produce the same effects? Dr. J. W. Moore gives a good account of Typhus Fever, which, owing to its "uncertain" bacteriology finds itself widely separated in this work from the disease with which it was for long wont to be confounded. Dengue is claimed by Dr. P. Manson in his account of this affection to belong to the class of exanthemata, whilst its resemblance in many aspects to influenza is well brought out. Yellow Fever is decribed by Dr. Andrew Davidson, to whom also is assigned the article on Dysentery. In another part of the volume there is an article upon Amœbic Dysentery by Dr. Lafleur, and this reduplication suggests not only the possibility of more than one causative influence productive of practically similar effects, but also goes to show that our knowledge of the pathogeny of this disease is in a state of transition. The remarkable affection, Beri-beri, upon which much fresh knowledge has been obtained of late is dealt with by Dr. P. Manson, who considers that its neuritic nature is amply proved, no satisfactory evidence having been adduced in favour of its homology with ankylostomiasis or anæmic dropsy, the dropsical character of the "wet" form of the disorder being obviously a superadded phenomenon. But the essential cause of beri-beri has not yet been discovered. The other articles in this part of the work are those on Malta Fever, by Dr. Lane Notter; Epidemic Dropsy, by Dr. Kenneth MacLeod; Negro Lethargy or Sleeping Sickness, by Dr. Manson; whilst Mr. R. H. Firth contributes those on Oriental Sore, Verruga, and Frambœsia. Next in order come the diseases which are communicable to man from animals, and of these glanders and anthrax, which have been proved to depend on specific micro-organisms, are taken first. Dr. Sims Woodhead writes on Glanders, first describing the affection in the horse, and then as it affects man, where it mostly appears in the form of farcy. The pathological lesions in the lungs and the bacteriology of the disease receive full attention. Dr. J. H. Bell writes upon anthrax, the elucidation of which disease marks the starting-point of the modern study of bacteriology as a factor in disease. The clinical descriptions of malignant pustule and of woolsorters' disease are excellent, and the importance of measures of prophylaxis in trades having to do with skins and hides is strongly urged. The articles which deal with the subject of Vaccination are amongst the most important in the book, embodying as they do the results of the extended inquiries which have been conducted at the

Hosted by Google

instance of the Royal Commission on Vaccination. To Dr. T. D. Acland we are indebted for an essay entitled "Vaccinia in Man: a Clinical Study," for which we venture to think there is no equivalent in previous writings on the subject. For the amount of detail, in the method of discussion of the facts, and the impartial as well as thorough manner in which the subject has been treated by Dr. Acland, he deserves all praise. The amount of painstaking labour which must have been expended in the investigation of cases of alleged injurious effects cannot be known until the long delayed Blue Book which forms one of the appendices to the Commission's Report is published, but we can form some estimate of it in the perusal of this article. The distinction drawn between invaccinated erysipelas and erysipelas obviously secondary to the operation is clearly shown, the greater number of this and other inflammatory complications obviously falling under the latter category. But it is not possible here to review adequately the contents of this essay. It must suffice to observe that after dealing with the phenomena of vaccination, the author describes the rashes incidental to it, the injuries which may be produced by it and the relationships between vaccination and syphilis and other inoculable diseases. It is abundantly clear from the facts adduced by Dr. Acland that vaccinal syphilis is the rarest possible accident, and that the risk of conveyance of leprosy or tubercle is almost, if not quite, as problematical as is that of cancer. Dr. Acland's contribution is followed by one by Dr. S. M. Copeman on the Pathology of Vaccinia. The interesting studies by Dr. Copeman make this exposition of the vexed question of the precise connexion between variola and vaccinia very valuable. The subject is one of great difficulty and it would appear as if it would never advance beyond the region of theoretical argument until the bacteriologist succeeds in demonstrating the organism which analogy suggests must be the cause of these affections. The value of Vaccination as a Branch of Preventive Medicine is once more exemplified by Mr. Ernest Hart, who introduces into the argument the additional statistical evidence supplied by the Final Report of the Royal Commission on Vaccination. It is incomprehensible to the ordinary mind that the accumulated facts of the efficacy of vaccination as a prophylactic and as a mitigating measure should still be disputed. Mr. Hart writes temperately, but strongly, in his exposure of the fallacies of the opponents of vaccination, and his demonstration of the inadequacy, not to speak of the cost, of alternative preventive measures is convincing. Dr. McFadyean writes on Foot-and-mouth Disease, and Dr. Sims Woodhead gives a most detailed account of Pasteur's work in his article on Rabies. This article is followed by a short account of Glandular Fever by Dr. Dawson Williams. Malarial Fever is described by Dr. W. Osler, the subject being treated in the light of the discovery of Laveran, so that it comes under the section of the work devoted to diseases due to protozoa. It is perhaps because of the close connexion between malaria and hæmoglobinuric fever, of which Dr. Copeman writes, that this latter affection is also placed in this category. Of Amœbic Dysentery no one can dispute the right to a place here, and the account given by Dr. Lafleur is valuable as coming from one whose researches have done so much to demonstrate the parasitic nature of the disease.

The next articles treat of subjects that bear more closely upon personal life and work, and will therefore perhaps be read with more interest. They deal with the intoxications, and embrace an account of Ptomaine Poisoning by Dr. Sidney Martin; articles on Grain Poisoning, Mushroom Poisoning, Opium Poisoning, &c., by the Editor; on Alcoholism, by Dr. H. D. Rolleston; on Snake-bite by Dr. C. J. Martin; and on Metallic and Other Forms of Poisoning by Dr. T. Oliver. Dr. Sidney Martin's account of ptomaine poisoning is useful, as suggesting a wide conception of the dangers of food that has undergone putrefactive or other change; for the reader is naturally led to think of the various symptoms and affections that have been ascribed to intestinal auto-intoxication as being in close alliance with these mysterious toxins, not to mention the so-called idiosyncracies which exemplify the truth of the proverb that "one man's meat is another's poison." In Professor Clifford Allbutt's article on grain poisoning we learn that Dr. Ehlers, a recent writer upon ergotism, has raised the question whether Raynaud's disease may not be of this nature. Professor Allbutt, however whilst admitting that there is room for criticism of Raynaud's work from this point of view is inclined to think that Raynaud himself "did not overlook the possibility of ergotism in his cases and decided against this poison." The article on snake poison and snake-bite is full of information, and comprises an account of the important researches of Professor Calmette and Profesor Fraser upon anti-venomous serum, Professor Calmette himself contributing an appendix to the article descriptive of his work. Of the article on alcoholism by Dr. H. D. Rolleston, it is impossible to speak too highly, and no one can read either this article or those from the pen of Professor Clifford Allbutt on Morphinism and Cocainism, without deriving much information and being gratified by the outspoken manner in which they are treated. Nor is it necessary to say anything in commendation of Dr. Oliver's work. He is a recognised authority on trade poisons and he gives the profession here the fruits of his experience and knowledge. The volume closes with descriptions of Parasitic Worms by Dr. Manson, Psorospermosis by Dr. J. Griffiths, and separate articles on Bilharzia by Dr. Guillemard and on Hydatid Disease by Dr. Verco and Dr. Stirling. In this cursory review of a volume of great and varied interest we have, we trust, said enough to show our appreciation of the amount of scientific information that it imparts. The work is one which reflects great credit upon British medicine. We venture to think that when completed it will take a prominent position in the ranks of treatises of similar scope, and that indeed it will be found to be of more enduring value than some that are more pretentious in their encyclopædic character. The editor is to be congratulated on having secured for his staff of contributors so goodly an array of writers, and these, too, deserve thanks for the evident pains that have been taken to ensure accuracy of treatment, fulness of knowledge, and clearness of exposition.

OPENING OF A NEW CONVALESCENT HOME OF THE NORTH-EASTERN COUNTIES' FRIENDLY SOCIETIES AT GRANGE-OVER-SANDS, LANCASHIRE.—This home was opened by Sir James Laing on the 9th inst., and is the realisation of a scheme, propounded in 1888 by Dr. William Robinson of Sunderland, by which the members of the various friendly societies have combined to procure a home on the West Coast for themselves by each contributing a small annual sum (sixpence or a shilling) for its maintenance. Grange-over-Sands was recommended for the site because of its beauty and of its being sheltered on the north and east by hills, and because there the home can be used all the year round and for all kinds of diseases, especially those of the chest in the winter months. The home is an elegant structure, situated amongst most lovely scenery and overlooking Morecambe Bay. It has accommodation for thirty-eight males, but can hold fifty, and is capable of great extension with its two acres of land. The cost of erection has been £3600, of which sum there remain £1300 still to be raised. A feature of the home is that when not filled by subscribing members outsiders are admitted at the rate of sixteen shillings per week. The secretary is Mr. W. C. Hetherington, 12, Vicarage-terrace, Sunderland.

Analytical Records
FROM
THE LANCET LABORATORY.

TABLOIDS—(1) RED GUM, (2) "SAXIN."

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, E.C.)

THE effective astringent properties of the red-coloured exudation of the *Eucalyptus rostrata* are now well recognised. As a local and general astringent, especially for relaxed throat, the drug may be favourably administered in tabloid form, since in this conglomerate state the astringent principles dissolve slowly in the mouth, thus ensuring a continuous and uniform application to the mucous surfaces. While distinctly astringent the red gum tabloid is by no means unpleasant in the mouth. "Saxin" is the name now applied to a sweetening agent the sweetening power of which is said to be 600 times greater than that of sugar, so that a tabloid weighing only a quarter of a grain may be substituted, for sweetening purposes, for an ordinary-sized lump of sugar. Thus in this form the equivalent of 100 or even 200 lumps of sugar may be carried in the waistcoat pocket.

COCA WINE—(1) ALCOHOLIC, (2) NON-ALCOHOLIC.

(BEAUFOY AND CO., SOUTH LAMBETH-ROAD, LONDON, S.E.)

The important feature of both these wines is that they are prepared with the extract of coca leaf, and not with the separated alkaloid. Proof of this was evident from the delicate leafy flavour of the wine and from the fact that both contained chlorophyll. The analysis of the alcoholic wine, the basis of which is a British wine, was as follows: Alcohol by weight, 12·77 per cent.; by volume, 15·77 per cent.; extractives, 13·80 per cent.; mineral matter, 0·31 per cent. The mineral residue was of a brown tinge from the presence of iron. The non-alcoholic sample was a sweet, somewhat syrupy, liquid with a pronounced taste of coca leaf, the basis being raisin wine. It is somewhat heavily preserved with salicylic acid, as was proved by extraction with ether in the acidified liquid. As with the previous specimen, cocaine in important quantity was successfully extracted. Both wines are genuine preparations and well adapted for the administration of the tonic and stimulating principles of the coca leaf. The non-alcoholic wine is a good substitute for, and suited to, those who prefer a non-alcoholic liquor, but in the absence of alcohol the preparation requires a preservative.

(1) BEEF JUICE; (2) GLYCERINE EXTRACT OF RED BONE MARROW.

(ARMOUR AND CO., 59, TOOLEY-STREET, LONDON, S.E.)

As our analysis shows, this beef juice is a powerful nutrient, since it contains not only the unaltered albumin of fresh, uncooked beef, but also a definite proportion of easily assimilable peptones as well as an important amount of the stimulating meat extractives. The proximate results of analysis were as follows:—Organic matter 19·32 per cent.; mineral matter (salt and soluble phosphate), 6·26 per cent.; water, 74·42 per cent. The organic (nitrogenous) matters (19·32 per cent.) proved to contain 5·74 parts of albumin (dried) coagulable in boiling water, 4·46 per cent. peptonic matter, and 9·12 parts of meat extractives. The flavour of the juice is good and pleasantly "beefy." As a rapid restorative and nutrient it is clearly on these data reliable. The glycerine extract of red bone marrow is a brownish-red syrupy liquid, possessing the peculiar faint and somewhat disagreeable smell of marrow extract. On the addition of dilute ammonia it turns to a bright blood red, and then exhibits the very marked absorption spectra characteristic of hæmoglobin. Its employment in anæmia and leucocythæmia has been attended with excellent results, as shown in a series of clinical records submitted to our notice.

NON-SACCHARINE PALE ALE.

HARVEY AND CO., PELLON BREWERY, HALIFAX. LONDON: BURGOYNE, BURBIDGES AND CO., 12 AND 16, COLEMAN-STREET, E.C.)

IT is quite true, according to our examination, that this beer is free from sugar. It is also practically free from any important amount of extractives, and in this particular therefore differs from the composition of ordinary malt liquor. It is, however, an alcoholic beverage, as the following analysis which we have made, shows:—Alcohol by weight 5·87 per cent., by volume 7·32 per cent., equal to 12·84 per cent. proof spirit; extractives, 0·73 per cent.; mineral matter, 0·05 per cent.; volatile acid equal to acetic acid, 0·04 per cent. The merit of this beer as a wholesome beverage is based upon its freedom from sugar. The question whether sugar has anything to do with gout is still a much debated point. Recent contributions on the subject refer more to the acidity of wines and beers as the more probable predisposing cause or as tending to produce acidity within the system. In any case this beer is practically free from both sugar and acidity. It posseses an agreeable, light, bitter flavour, and forms an acceptable beverage. The bitter is undoubtedly derived from the hop, but according to our analysis there is only a trifling proportion of extractive matters derived from malt. In view, however, of the class of consumers for whom this beer is primarily intended it is correctly offered as a drink without any pretence of direct nutritive properties, although obviously it may serve as an agreeable stomachic and tonic, and thus favourably influence the processes of nutrition.

MANHU CEREAL FOODS.

(IRVING, SON, AND JONES, 5, CHAPEL-STREET, LIVERPOOL.)

The list of Manhu foods embraces an excellent series of cereal preparations, and judging from certain specimens we have examined it clearly includes cereal foods in their entirety—that is to say, those which are not impoverished by any process of manufacture, but, on the contrary, those in which the processes of manufacture are such as to secure the maximum retention of the vital food principles. The faith of the public has too long been given to the idea that the whiter the loaf the purer the ingredients, and this has led largely to the supply of anæmic-looking flour and bread. Ignorance, however, in this matter is happily steadily declining, and it is satisfactory to notice the increasing demand for cereal foods, including bread, which do not bear the appearance of any important food substance having been abstracted, and which present a composition lacking nothing in the proportion of nourishing elements. The preparations before us include certain foods which have been granulated or flaked. This process does not detract from the nutritive value of the preparation, but, on the contrary, renders the constituents easier of digestion. Manhu wheat, oats, and barley (flaked) are excellent types of this order. Lastly, we have examined Manhu Infants' Food, which is partly digested by malting and by careful cooking; it therefore contains a high proportion of soluble carbohydrates, the indigestible starch being reduced to a minimum. The cold water solution responds freely to the dextrine reaction, while the proportion of glutinous material is excellent. The microscope reveals a mixture of flours, each contributing food value of its own specific kind. Not the least excellent result secured by this admixture is the high proportion of mineral matters, chief amongst which is to be reckoned the important soluble salt—potassium phosphate. The addition of milk to the preparation brings it nearer the ideal as a food specially adapted to the requirements of infants.

THE LANCET.

LONDON: SATURDAY, MAY 22, 1897.

THE session of the General Medical Council will commence at two P.M. on Tuesday next, and is likely to be in many ways interesting to the profession. The questions that must engage the attention of the Council are numerous and important. The whole of these cannot be anticipated till after the meeting of the Executive Committee on Monday next, at which the final form of the first programme of business will be prepared, for it is one of the functions of this committee to prepare, before each meeting of the General Council, the business for the consideration of the Council. But it is always possible by a reference to current events and to the business deferred at the last meeting to forecast in a great degree the more important subjects that will claim the attention of the Council. The unfortunate breakdown in the health of the Registrar during the last session of the General Medical Council will doubtless be reported on with a view to the future. The office is one of the greatest importance, alike in its responsibilities and in respect of the qualities required in the holder of it. There will be important changes in the *personnel* of the Council. The retirement of Mr. WHEELHOUSE and Sir WALTER FOSTER will be regretted by all their former colleagues. Their places will be taken by Dr. RENTOUL and Mr. GEORGE BROWN, unless, indeed, as suggested in his letter to Sir RICHARD QUAIN (published in THE LANCET of last week), Dr. RENTOUL'S engagements should only allow him to give one day to the May proceedings of the General Medical Council, and this only for the purpose of discussing one subject. It is to be hoped that Dr. RENTOUL will find himself more free to attend to the whole business of the Council than he suggests. Direct Representation will suffer discredit if it concerns itself with only one subject, however important that may be in the mind of any particular member. There would be curious results if each member of the Council bargained for a special day for the discussion of one subject and absented himself on other occasions. There is some difference between Dr. RENTOUL and the President as to the particular form and way in which Dr. RENTOUL will be in order in bringing the subject of Midwives' Bills before the Council. But this is a matter of detail on which there should be no difficulty in finding a solution. The many-sidedness of the question and the large part it played in the recent election of Direct Representatives make it reasonable that Dr. RENTOUL should have as full an opportunity as possible, consistently with the other duties of the Council, of submitting his views to the consideration of the members. There is another change in the membership to be noted, the replacement of Dr. ANGUS FRASER by Dr. ROBERT WILLIAM REID, Professor of Anatomy in the University of Aberdeen. It is impossible not to regret the absence of Dr. FRASER, who was a most useful member of the Education Committee, but it is a consolation that he is to be succeeded by a distinguished representative of anatomical knowledge. Sir RICHARD QUAIN'S unrivalled health has suffered impairment in recent months, but he is still showing evidence of the energy and interest in the affairs of the Council and the profession which have been so conspicuous for a generation, and he hopes to be able to discharge his duties as President in the coming session.

Among the chief questions that will occupy the time of the Council are the following:—The Order of the Privy Council in the matter of the Apothecaries' Hall, Dublin; the Reports of the Inspector of the Dental Examinations; a further Report of the Executive Committee on the Disciplinary Powers of the Medical Authorities; an interim Report of the Education Committee on the Best Means of Increasing the Stringency of Preliminary Examinations; a Report from the Examining Committee on the Need for Revision of the Regulations of Bodies Granting Dental Diplomas. The decision of the Privy Council in the appeal of the Apothecaries' Hall of Dublin from the General Medical Council, which it will be remembered refused to appoint surgical examiners to the Hall, is the first instance of anything like collision between the General Medical Council and the Privy Council. We do not anticipate any difficulty or hesitation on the part of the Council in accepting the ruling of the Privy Council. The authority of the Privy Council is supreme and its action towards the General Medical Council has always been friendly and respectful. The General Medical Council has discharged its own duty according to its lights on this question, but its lights and legal lights are not always synonymous and in the last result legal decisions must stand. Such collision must occasionally happen. It is creditable that it happens so seldom and does not frequently interfere with the harmonious working of the profession and the State for the public good. The reports on the Qualifying Examinations in Dentistry, or such of them as have not been already discussed, will form an early, if not the first, subject of the Council's attention. It is fit that they should, whether we regard the expense of the inspections, the importance of the subject, or the high qualifications of the inspector—Mr. CHARLES S. TOMES, F.R.S. It is too soon to expect any report of consequence from the Education Committee on increased stringency of preliminary examinations. But it is to be hoped that the Education Committee realises that there is no subject which the profession watches with more interest and unanimity. If the holocaust of medical failures cannot be mitigated in any other way, let it it be diminished by kindly severity at this early stage, disclosing to men, while it is time, their unfitness for medical study.

Sir RICHARD QUAIN may be expected to give us some account of the deputation appointed to wait on the President of the Local Government Board in response to the loose evidence on which local registrars are allowed to register the causes of death. This evil is a crying one and it is one which lies at the very root of much irregular practice disastrous to the health of HER MAJESTY'S subjects; moreover, it has its bearings on the system of employment of unqualified assistants which is now out of date, and in regard to which many

Hosted by Google

members of the Medical Council think that the time has come for more determined action. As regards penal cases there is little on the surface to report.

WE have no reason to complain of the long and instructive debate which has taken place in the House of Lords on the very important subject of the health of our troops in India. The Earl of DUNRAVEN introduced the motion that led to this debate, which we rejoice to observe was conducted in an eminently fair and excellent spirit throughout. A great change has taken place in public and political feeling since 1888, when the House of Commons passed what we regard as their ill-advised resolution, to the effect that "any mere suppression of measures for compulsory examination of women, or for lessening and regulating prostitution in India, is insufficient, and the legislation which enjoins, authorises, or permits such measures ought to be repealed." All that has since taken place has served to enlighten the public mind and to convince reasonable people that the result of the Parliamentary action then taken has been most unfortunate. The Earl of KIMBERLEY, who was Secretary of State for India at the time, fully recognises that it is our absolute duty to take any measures we can devise for diminishing the frightful amount of sexual disease that has been shown to exist in the Army in India. Holding as we do with the Earl of ONSLOW that the time for further inquiry—which cannot, after all, alter the broad and established facts of the case—is past, and the time for action has arrived, we are not sorry that Lord DUNRAVEN asked leave to withdraw his motion. The last thing he wished for, he declared, was that action should be delayed.

The Government occupy a safe and firm foothold in regarding this class of disease as belonging to the category of contagious diseases and as one to be dealt with accordingly. The facts that have been brought to light demand that prompt action of some kind should be taken. If the safeguards that were formerly in force failed, either from inherent defects or from improper working, to effect all that was expected of them, as has been alleged, it has at any rate been demonstrated that they nevertheless exercised a material restraining influence. The views of THE LANCET on this question are too well known to need any repetition of them now. We have always contended that, in the interest of public health and in the cause of humanity alike, restrictive measures of some kind were both necessary and benevolent—and especially as far as the unfortunate women are concerned; that there was logically no reason why a contagious and hereditary disease like syphilis should be made a privileged disease, and allowed to contract itself out of the Act dealing with other contagious, but less insidious, far-reaching, and dangerous maladies, such as typhoid fever and small-pox for example; that it was a national question, and not at all one of any political party; and that its treatment needed to be approached and proceeded with on two lines of action—the physical and hygienic as well as the religious and ethical—its scientific and moral sides. We have never shut our eyes to the difficulties that had to be encountered and overcome in the application of any proposed remedial measures, or to the need that exists for the Government proceeding warily in a matter about which so much ignorance, prejudice, and false sentiment prevail. We might truthfully go even further, and say that the main difficulty in dealing with this subject arises from a false reticence and cowardly indisposition to face the facts which are practically in the experience of all of us. We must regard human nature as it actually is and not as it should be. The sexual instinct is the strongest and most dominating instinct implanted in man, especially imperious at a time when his will-power and moral force are weakest. As the Duke of CAMBRIDGE with an outspoken frankness expressed it, "You must change human nature before you can get rid of the vice altogether." We know that of late years great efforts have been made to improve the social, educational, sanitary, and moral conditions of the Army in India with, unhappily however, but little immediate effect in this respect on our young soldiers in that country. By all means let those efforts be continued and developed, but that is surely no reason why we should neglect those physical means for restricting the spread of contagion which are direct and practical and of ascertained efficacy. In regard to these and the subject generally we have but little to add to what we have already said in previous articles, having so lately as April 10th last detailed the methods by which the evil might be practically dealt with in the way least offensive or objectionable to religious and ethical considerations.

The despatch of the Secretary of State for India, Lord GEORGE HAMILTON, is now in the hands of the Indian Government, and we shall soon learn what their proposals are. The debate in the House of Lords will strengthen their hands and indicate to them the lines on which these proposals should be based. The speeches in that debate were, in our opinion, excellent, and the subject was thoroughly threshed out from various points of view. Lord LISTER made his first speech as a member of the House of Peers, and he was, very naturally, listened to with marked attention and did good service to the subject and the State by what he said. The speeches of Lord ROBERTS, the Earl of ONSLOW, the ARCHBISHOP of CANTERBURY, Lord REAY, Lord PLAYFAIR, and the Earl of KIMBERLEY were all excellent in their way, and the statesmanlike, well-considered address of the Marquis of LANSDOWNE struck us as being especially good. We think the present Government are to be congratulated on the courage they have shown in honestly confronting this very difficult and important question and on the moderation and ability with which they have dealt with it. But the most encouraging and striking feature in the debate is the new and enlightened spirit in which it was conducted.

THE Metropolitan Police Court Bill now before the House of Commons, under the charge of Mr. JESSE COLLINGS, affords a rare opportunity of redressing a grievance of which the General Medical Council has long and sorely complained, and the continuance of which is, in fact, highly injurious to the public interest. Under the Medical Act of 1858 certain fines

Hosted by Google

are authorised for false pretences of qualification. Clause 42 enacts "that any sum or sums of money arising from conviction and recovery of penalties as aforesaid shall be paid to the treasurer of the General Council." This is a very clear indication of the intention of Parliament that the General Medical Council should have the fines so accruing. Our readers will be surprised to learn that in the metropolitan area these fines never reach the General Medical Council, and that under the Metropolitan Police Acts they are appropriated by the Government for the expenses of the Police-courts. In all other parts of the country but the metropolitan area the fines go, as the Medical Act directs, to the General Medical Council. If the Council is not itself the prosecuting body it hands over the fines to any persons who, or association which, may have had the trouble and expense of the prosecution. This grievance has been complained of by the General Medical Council for over twenty years. In May, 1891, a motion on the subject was proposed by Dr. GLOVER, and seconded by Sir JOHN SIMON, setting forth the grievance, and a deputation was appointed, on the motion of Sir WALTER FOSTER, seconded by Dr. HERON WATSON, to wait on the Home Secretary, Mr. MATTHEWS, to seek redress. Mr. MATTHEWS evinced much sympathy with the deputation and admitted the grievance, but said that it was then quite impracticable to alter the arrangement, as in London the courts were maintained at great cost by the Treasury, whereas in other parts the expenses were paid out of the rates. He promised further consideration of the evil and held out hope that eventually the charges of the metropolitan police-courts would, as in the provinces, fall on the local authority, when there would be no excuse for the retention of the penalties by the police-courts.

The Bill of Mr. JESSE COLLINGS, now referred to the Standing Committee on Law, seems to afford a favourable opportunity for effecting the removal of this long-felt grievance. Accordingly, Sir RICHARD QUAIN and Dr. GLOVER have been using their best endeavours, though the General Medical Council is not sitting, to utilise the occasion. They have met, we understand, with much assistance from Sir WALTER FOSTER, Sir WILLIAM PRIESTLEY, and Dr. FARQUHARSON, and also from Mr. BUCKNILL, Q.C., who is a member of the Committee on Law. There is, therefore, some hope that the intention of the Legislature in the 42nd Clause of the Act of 1858 may not further be frustrated. For frustrated it effectually is by the present state of the law, the judges having ruled that as the Medical Act did not specially repeal the Metropolitan Police Act in this respect the latter holds good as against the later Act. The consequence is obvious. Such bodies as the Medical Defence Union and the London and Counties Medical Protection Society are discouraged from undertaking prosecutions against offenders in the metropolitan area. Here the worst offenders thrive with impunity and with disastrous results to the health and morals of the people of all classes.

It is devoutly to be hoped that Her Majesty's Government will see the reasonableness of accepting a clause in this Police Finance Bill which will give validity to the 42nd Clause of the Medical Act (1858) within the metropolitan area. All attempts to get the Public Prosecutor or the police to undertake the prosecution of offenders under the Medical Acts have failed and are likely to fail. The least the Government can do in these circumstances is to help to secure for the General Medical Council the fines which the law contemplated being used for the payment of those who do the duty which the Government declines. On the very same day that this Bill was under discussion the Government heartily accepted a proposal that the Incorporated Law Society should receive about £5000 per annum as a portion of the expenses incurred by the Society in the discharge of its disciplinary duties, recognising that in the discharge of such duties it is acting in the public interest. *A fortiori*, the prosecution of the worst and most fraudulent quacks is work done in the public interest and intended to be paid for out of the penalties imposed in the Medical Act. No such charge on the Treasury will be involved in the insertion of a clause in Mr. JESSE COLLINGS'S Bill. The operation of the present law is to prevent all prosecutions. We trust Mr. COLLINGS will see his way to accept a clause remedying such an absurd state of affairs.

Annotations.

"Ne quid nimis."

THE PRINCESS OF WALES AND THE POOR.

AMONG the many charitable schemes which have been started and carried to a successful conclusion as memorials of the sixty years' reign there is, perhaps, none the apparent benefit of which will be more immediately realised than that provided for by the Princess of Wales's Fund. An anonymous donor has just subscribed £25,000 to make up the required sum, and it is hoped that the whole of the poor in London will get at least one good meal at the Jubilee season. We have no details at present as to how the scheme of feeding these poor people is to be carried out, and in our opinion a vast amount of careful organisation will be required if the project is not to end in failure. That there is a terrible depth of bitter poverty in London no one can doubt, but as a rule it is just the most deserving who hide their misery and prefer to suffer in silence. Will any steps be taken to seek out the really deserving, and, more important still, will there be any attempt to confine the dole to the poor of London alone? If something of this kind is not attempted every scoundrel and loafer—all those who have never done any work and never mean to do any—will come from all parts of the kingdom and batten on the charity provided. This was the case some years ago when the Mansion House famine fund was started, the metropolis was inundated with provincial tramps and there was great doubt as to whether the really needy profited at all. Another matter of vital importance is the likelihood of the spread of infection by the gathering together of those who, owing to their mode of life, are most prone to contract and disseminate infection. The revelations made some year or so ago by Dr. Waldo about Salvation Army shelters showed that even under ordinary circumstances the crowding together of the homeless was anything but free from danger, and such danger will be multiplied a thousandfold in the coming month. The most careful watch should be kept upon all lodging-houses and workhouses on the roads leading into London as well as in that city itself and we think that some attempt should be made to see that the food supplied does not go to fill the bellies of those who make a trade of

Hosted by Google

poverty. Unless something of this kind is done the distribution may do more harm than good. In the meantime all we can do is to await the publication of details as to the management of the fund.

THE DISASTER AT SNAEFELL AND A REMARKABLE SEQUEL.

A SADDER disaster than that which occurred in the lead mine at Snaefell last week, by which some twenty persons lost their lives, can hardly be imagined. They simply descended into a lethal chamber, so to speak, and were overtaken by a deadly gas. The occurrence of so highly poisonous an atmosphere in a lead mine is a revelation, and only accentuates the extreme desirability of completely and continuously ventilating all sunken shafts and their ramifications. The origin, and to some extent the nature, of the poisonous emanation is still involved in some mystery; but by an alarming incident which occurred to a gallant party intent on the recovery of bodies some further light has been thrown upon the intensely insidious properties of the gas in the mine. This party, consisting of Dr. Foster, Her Majesty's Inspector of Metalliferous Mines, with his assistant, Mr. G. J. Williams, Captain Reddicliffe, and Captain Kewley, of the Snaefell mine, and eight others, proceeded to make a descent to recover the only body remaining in the mine. Pilot candles were lowered to ascertain the condition of the air, and it was shown that they burned brightly at 115 fathoms, but were extinguished at 130. In this way the explorers were able with due caution to arrive at within twelve feet of the body, but the air immediately below proved to be highly poisonous. One of the party, however, Captain Kewley, ventured to lower himself further with a view of catching the clothing of the body with grappling irons; but the deadly gas was stirred up by this procedure, and Captain Kewley was at once overcome and was hauled back to the landing. This venture very nearly cost the lives of the rest of the party, for the gas began to seriously affect them also, and so they vigorously rang the bells for assistance and as a signal to hoist the travelling box to the surface again. For some reason or other the box got stuck on its journey up with Captain Kewley in it, and the party below were threatened with entombment. All this time Dr. Foster made notes. In these he wrote a "Good-bye" to all his friends, and added, "I fear we are all dying. No help coming. The box does not come. In spite of all our ringing for help it will not come. Captain Reddicliffe is struggling. No real pain. Good-bye. I feel as if I was sleeping. Again good-bye all. 2.15 P.M., we are all done. Oh, for the box. It is held in the shaft." He added a further note to his wife saying good-bye to her and their children, concluding with: "It is really like a bad dream. No pain. No pain. For the benefit of others, no pain." At length there were indications that the box had gone up and Captain Kewley was hauled to the surface, and in due course the rest, after a most painful period of suspense, were likewise released. When Dr. Foster arrived with note-book in hand he was very weak and staggering, despite which he made an entry recording the time of his release. It is a beautiful and touching story, and is eloquent testimony that heroism is still with us. There would appear to be strong evidence in favour of the view that the deadly poison was carbon monoxide, probably associated with the much less deadly, but still distinctly toxic, carbonic acid gas. The fact that the gas readily ascended on being merely disturbed with grappling irons indicates, however, that it was not of the heavy character of carbonic acid, which is one and a half times heavier than air, whereas carbon monoxide has about the same density as air. The bodies of the poor fellows brought to the surface presented that pink appearance so characteristic of carbonic oxide poisoning. Again, Dr. Foster appears to have murmured, as it were, in his notes, "No pain, no pain." There was apparently no distress due to panting — a symptom distinctly connected with carbonic acid poisoning; while, on the contrary, with carbon monoxide the senses are gradually more and more benumbed, as Dr. Haldane has shown, as by a gentle anæsthetic, very little actual distress accompanying the action. Later we learn that Dr. Haldane has proved the gas to be carbon monoxide. Here is one consoling reflection; the poor miners who succumbed probably died a painless death, passing gradually into stupor and to sleep, and from sleep to death. The origin of the carbon monoxide in this instance is most obscure, but it has been suggested that it may have been due to the comparatively slow combustion which had by some means been started of certain explosives used in the mine for blasting purposes. Possibly the gas had its origin in a volcanic disturbance. As regards this point we can only wait until a rigid exploration of the mine—as soon as its channels are safe—has been conducted. In the meantime the suggestion contained in the *Isle of Man Daily Times* that the money available for the local Diamond Jubilee Fund should be directed to the relief of the distress occasioned by this awful calamity is a most admirable one, and we are quite sure that it would meet with the strongest approval of our Gracious Sovereign, whose sympathies in the alleviation of distress are well recognised and appreciated.

ANOTHER "PLAGUE AT ATHENS."

HISTORY repeats itself, and if the correspondents of our lay contemporaries are right we are in imminent danger of witnessing another "plague at Athens" similar in cause, if not in symptoms, to that depicted for all time by Thucydides. Whatever the origin of that fearful visitation (whether from Ethiopia, and thence through Egypt and Libya), one most powerful cause of its effecting a foothold in Athens was the overcrowding of the city with fugitives from before the advancing Peloponnesians. "The extraordinary accumulation of people within the city and long walls was but too favourable to every form of contagion. Families crowded together in close cabins and places of temporary shelter throughout a city constructed with little regard to the conditions of salubrity, and in a state of mental chagrin from the forced abandonment and sacrifice of their properties in the country, transmitted the disorder with fatal facility from one to the other. Beginning about the middle of April, the increasing heat of the summer further aided the disorder, the symptoms of which, alike violent and sudden, made themselves the more remarked because the year was particularly exempt from maladies of every other description." As above narrated, the conditions of Athens 430 B.C. are curiously similar to those of the same city A.D. 1897; these are the flight from a victorious enemy, the poverty, the panic, the overcrowding, the depressing emotions so favourable to the inroads of epidemic disease, and the unpreparedness of the civic authorities for such a strain on their resources, in a city, moreover, if less insanitary than it was in the fifth century before Christ, still very backward as compared with other European capitals. The outbreak of such another plague would be the culmination of the misfortunes and the miseries under which the Hellenic kingdom is now labouring, and the Powers would do well to add to their pacific intervention a hardly less required series of measures for keeping at bay the threatened invasion of disease. If the visitation, as described by Thucydides (on which, by the way, medical historians are not agreed—Littré, for instance, calling it variola and Hirsch "ein Gemisch verschiedener Krankheiten"—a combination of different diseases), will find no parallel in the contemporary one now dreaded, the forecast is sufficiently

Hosted by Google

grave to justify the most energetic precautions. Communication, moreover, between Greece and the Mediterranean ports is infinitely more frequent and extensive than in the days of Pericles, and localisation of disease is correspondingly difficult. On every ground—on that of solicitude for the Hellenic capital in its deplorable condition as well as on that of common self-interest—the Powers are called upon to exercise hygienic as well as diplomatic vigilance, and we hope the response will be such as the situation suggests and humanity indicates.

THE MEDICAL OFFICER OF HEALTH OF THE COUNTY OF DURHAM.

THE annual meeting of the Durham County Council was held at the Shire Hall, Durham, on May 5th, Alderman Arthur Pease presiding. The health committee's report mentioned that Dr. Hill, the county medical officer, had made an application for an increase of his salary, and the report went on to say that Dr. Hill had held the office for five years, that his duties had been most satisfactorily performed, and that the committee recommended that his salary be increased from £500 to £700 per annum. Alderman Livingstone, in moving the adoption of the report, eulogised Dr. Hill's work, and stated that other county councils paid their medical officers as follows—Essex £800, Derbyshire £600 and £200, Shropshire £750, Staffordshire £800, Surrey £1000, and Worcester £785. An amendment having been moved and seconded to the effect that the increase should be to £600 instead of £700, Alderman Storey pointed out that the difference between £600 and £700 a year for a county with a population of 720,000 and a rateable value of £3,250,000 was not large, and that the payment of the smaller sum put a premium on Dr. Hill's leaving them and thereby disturbing the health arrangements of the county. In the result the amendment was lost by a large majority, and the committee's recommendation that the salary should be £700 was consequently carried.

THE EFFECT OF THE ROENTGEN RAYS ON THE TUBERCLE BACILLUS AND ON DIPHTHERIA TOXIN.

THE question whether the Roentgen rays exert any influence on bacterial life is of considerable interest, and conclusive evidence on at least a part of the subject seems to have been arrived at by Dr. J. Brunton Blaikie, President of the Edinburgh Royal Medical Society. His experiments, published in the current number of the *Scottish Medical and Surgical Journal*, were as follows. Portions of glycerine agar having been placed in small boxes of aluminium, which is more transparent to the rays than glass is, they were sterilised and inoculated with streak cultures of the tubercle bacillus. At the same time four healthy guinea-pigs were inoculated with twice the minimum lethal dose of diphtheria toxin, and the remainder of the diphtheria toxin was placed in another aluminium box. Three of the boxes containing tubercle cultures, two of the guinea-pigs, and the box with the toxin, were placed under the full influence of the rays generated by a 4-in. spark coil and a good focus Crookes's tube. It was necessary to stop the current occasionally, as otherwise there would have been danger of injuring the tube, and on this account, although the subjects of experiment were placed immediately under the Crookes's tube for a working day of about thirteen hours, they received only eight hours of actual exposure to the rays. Next morning two more guinea-pigs were inoculated with the toxin which had been subjected to the rays. The following was the result of the action of the rays on these guinea-pigs: two that were exposed to the rays after inoculation with twice a lethal dose of toxin lived respectively for 101 and 55 hours after inoculation. Two that were inoculated with twice a lethal dose of toxin, but not exposed to the rays, lived respectively for 120 and 76 hours after inoculation. Two that were inoculated with five times a lethal dose of toxin which had been subjected to the rays lived respectively 45 and 60 hours. From the above results it is seen that the guinea-pigs subjected to the rays lived actually a shorter time than the others, and that the toxin through which the rays passed did not lose its lethal properties. All the guinea-pigs showed the ordinary signs of death from diphtheria toxin, the only difference among them being that the hair of those through which the rays had passed could be pulled out with unusual ease. The cultivations of tubercle bacillus all grew in the ordinary manner, so that they were evidently not affected by the rays.

A CURIOUS POINT OF LAW.

A SOMEWHAT novel action was recently tried in the Supreme Court, Melbourne, before Mr. Justice A'Beckett. A lady wished to have a marriage settlement set aside. The property was left upon trust after the lady's death for her children. It was sought to do away with the trust on the ground that it was impossible for children to be borne. Two lady practitioners gave evidence that it was a physical impossibility that children could be borne. His Honour, after reserving judgment, called in Dr. Balls-Headley as a medical assessor to determine the medical questions involved, who reported that, "while the birth of a child which might attain the age of twenty-one years was not probable, it was not impossible." His Honour accordingly adopted the view of the evidence taken by the medical assessor, and would not set aside the settlement. At a later period, should the plaintiff continue childless, the Court might be able to do what it could not do now, and leave was reserved to the plaintiff to apply to have the funds transferred to her hereafter.

EDINBURGH UNIVERSITY CLUB.

ON May 12th the Edinburgh University Club held its usual quarterly dinner in the Holborn Restaurant, under the presidency of Lord Lister. The fact that this was his lordship's first appearance in the club since his elevation to the peerage accounted for the large company of over 200 who were present to do honour to the distinguished chairman. Among the guests were Sir John Evans, Dr. Michael Foster, Dr. Clifford Allbutt, Mr. Bryant, and Mr. MacWhirter, R.A. In proposing the toast of "Alma Mater and Prosperity to the Edinburgh University Club," Lord Lister referred to the annotation in THE LANCET of May 1st and the subsequent correspondence on the Decline of the Scottish Universities. He said that he did not entertain such gloomy feelings as were manifested in some quarters, for there must always be, as there have been in the past, ups and downs in the number of students in the Scottish universities. This fluctuation was due to various causes, some not easy to explain. Thus, for instance, he referred to the diminution about the time when Professor Allen Thomson left the Physiological Chair in Edinburgh to take up the position of professor of anatomy in Glasgow University. He also pointed out that the increase of medical students a few years ago was so great that a student had difficulty in getting a dressership, and sometimes had to be content with one-sixth of a bed. Such extremes as these were not easily explained. He admitted that the increase in secondary education of late years had its influence on the number of arts students, and possibly also the five years' curriculum and the corresponding increased expense might have recently influenced the number of medical students. As to the effect of the lecture system, he said that as a student at University College, London, which

Hosted by Google

was founded in imitation of Edinburgh, he had himself benefited by the system, but he was willing to admit that it might be overdone in some quarters. He emphatically declared that a point of extreme importance in the Scottish system is that the universities are true teaching ones in which the teaching and examinations are combined—a state of things incomparably superior to the mere examining universities, both as regards justice to the student in the examination, and still more in regard to the encouragement of legitimate study as compared with cramming. "The Guests" was proposed by Mr. McMorrine and acknowleged by Sir John Evans, Dr. Clifford Allbutt, and Mr. Bryant. Sir Joseph Fayrer proposed the health of Lord Lister, a toast which was received with great enthusiasm.

MEDICAL SOLIDARITY IN SPAIN.

THE spirit of union, to the somewhat lamentable lack of which in the ranks of the medical profession in this country we devoted a leading article last week, is said by a writer in a Bordeaux contemporary[1] to be the ruling power amongst the confraternity in Spain; and not only do practitioners of every degree unite in that happy land to repel all attacks on the dignity or the interests of their calling, but the magistrates, being likewise duly imbued with a sense of responsibility, are wont to collaborate effectively with them in the pursuit and suppression of charlatans. In support of his thesis the reporter refers to the medical college at Barcelona, where, in addition to watching over the material and moral well-being of their alumni, the authorities also strive in every possible way to elevate and sustain medical prestige. Included among their most cherished institutions there is a special committee which is charged with the detection of fraud and the submission of suspicious cases to the legal tribunals. This body sits in permanent session, and so gentle has been its spiriting that both the governor of the province and the Royal procurator afford it their countenance and take an official interest in its proceedings. The special committee is, moreover, in possession of an unlimited credit and, besides maintaining a trained corps of investigators, is empowered to add to its *personnel* whenever such a measure may seem to be desirable. The fulminations of this liberally endowed board of control are directed against all persons, male or female, whose acts may seem to infringe upon the medical or the pharmaceutical prerogatives, the offenders for the most part being masseurs and masseuses, herbalists, hypnotists, bone-setters, faith healers, &c. Priests, too, are not unfrequently included in the black list of irregular practitioners of medicine, which last year is said to have contained seventy names. But it is not against empirics alone that the Barcelona College wages war, for, as the following public notice shows, qualified men who commit ethical sins are equally liable to reproof: "The special committee, duly authorised by the College, finds itself under the painful necessity of drawing attention to the fact that Drs. X, X, and X, forgetful of their social and professional obligations and wilfully ignoring the dignity and the moral interests of their respective corporations, assist and encourage charlatanism and illegal practice by placing themselves nominally at the head of the institutes, dispensaries, or clinics situated at such and such addresses, while these establishments are, in reality, conducted by the individuals named Z, Z, and Z, pretenders devoid of all knowledge and legally incapacitated from exercising the healing art. The special committee further declares that before the publication of the present notice attempts were vainly made by courteous representations to divert the medical gentlemen concerned from their dangerous courses. The authorities of the college unanimously invite the public, thus enlightened, to avoid these disreputable establishments, and they moreover beg their honourable *confrères* to suspend all professional relations with the incriminated practitioners." The colleges of Madrid and Navarre, which go hand in hand with their congener of Barcelona, are seeking to modify the penal code with a view to increasing the punishment for practising medicine irregularly. They also recommend the appointment of a Secretary of State for Medical and Sanitary Affairs, who shall act as public prosecutor, and they strenuously urge the obligatory attachment of all practising medical men to colleges for disciplinary purposes.

[1] Gazette Hebdomadaire des Sciences Médicales, May 9th, 1897.

THE INTERNATIONAL CONGRESS OF PHARMACY.

THE Eighth International Congress of Pharmacy, as we announced last week, will be held at Brussels from Aug. 14th to the 19th. Three prizes will be given for the three best papers upon Pharmacy from a Practical and Scientific Point of View. Three others will be given for the three best papers dealing with professional subjects. Pharmacists, medical men, and chemists are eligible to compete. Further information will be given by the Secretary, M. Duyk, 102, Chaussée de Wavre, Ixelles, Brussels.

THE DEATH FROM ANTHRAX AT SALTAIRE.

AN inquest was recently held by Mr. Barstow upon the body of a wool-sorter's labourer, aged sixty-two years, who died from anthrax, contracted while following his employment at Saltaire Mills. There is nothing very remarkable about the case, which was one of a nature only too common and rapidly fatal. The disease was apparently contracted from the dust of a warehouse which the deceased had to sweep out, and the wool stored therein came from Van. Fans were in use in the mill to carry away the dust, in accordance with the regulations of the Board of Trade. The jury, in returning their verdict, made a recommendation that the floor should be sprinkled with a disinfectant solution both before and after sweeping. It surely ought to be possible to disinfect the bales of wool in some apparatus before opening them, and thus reduce the dangers to a minimum. We do not pretend to be experts in the processes necessary for converting wool into cloth; but we should say that some sort of apparatus, like that described in THE LANCET of Jan. 11th, 1896, could be employed, and would not injure the finest quality of wool. Anthrax is so deadly a disease that it is only right that every means of keeping it in check should be employed.

NON-INFLAMMABLE FABRICS.

A PRACTICAL experiment recently made on the site of the old Millbank Prison before a number of distinguished people would seem to have demonstrated that it is possible to make wood non-inflammable. The process appears to consist in injecting certain chemicals into the wood after the removal of the sappy constituents. We assume that the *rationale* of this process is probably that by the impregnation of wood with easily fusible salts it is rendered hard to ignite, because on the approach of heat these salts would become fused and enclosing the woody fibre, protect it from igniting. If success has been attained on these lines cheaply and without difficulty, it is of far reaching importance in connexion with the sad losses of life incurred every year in the conflagration of dwelling-houses. The recent calamitous disaster at Paris is still fresh in our minds, and the shocking deaths, at least from burning, might, to a very large extent, have been averted had the building been constructed of comparatively non-inflammable material. But previously to the disaster there were materials employed in the interior of the building of far higher inflammability than the wood of the building itself or even the tarred roofing. We refer to the long lengths

Hosted by Google

of celluloid films used for depicting the photographs in the kinematograph. Cannot something be done to make the viciously inflammable celluloid non-inflammable without impairment of its transparency? Celluloid, which, by the way, is a nitro-compound, is being largely employed as a substitute for ivory, horn, &c., in the manufacture of many articles of every-day use, and the record of accidents, and even fatalities, arising from its exceeding tendency, not only to flame, but to burn with almost explosive violence is increasing day by day. The usefulness of this substance cannot be doubted, but some endeavour should be strenuously made to render it in the interests of the public safety less inflammable.

THE LIMITATIONS OF CHARITY.

A LETTER which appears in the *Times* of May 17th from the Duke of Westminster reminds us that the river of charity is not inexhaustible. His Grace says "that owing to other claims the ordinary streams of benevolence have left their usual channels" and that the Metropolitan Drinking Fountain and Cattle Trough Association, of which he is president, is accordingly suffering so from want of funds that it will have to close a number of troughs if aid is not forthcoming. We do not doubt that this association is not the only one to suffer from the same causes. While on the subject of kindness to animals we should like to say a few words upon the abominable way in which those who ought to know better treat their horses in the matter of bearing-reins. Even supposing that a bearing-rein is a necessity in London, as some say, there can be no possible reason for having them so tight as they often are, or for keeping horses standing for long spaces of time without allowing them freedom. We frequently see an instance of abuse of this kind exemplified by a carriage and pair which waits near the Strand for an hour or so at a time, with the two unfortunate horses tightly reined up and obviously in discomfort. We shall not at present divulge the name of the noble owner, but only express a wish that some steps will be taken to remedy an unnecessary evil. If everyone who used a bearing-rein were compelled to pay a tax to be handed over to the society the poverty of which the Duke of Westminster deplores, either an abuse would be stopped or a deserving body would be freed from the curse of narrow means.

EXCISION OF PAROVARIAN CYSTS WITHOUT REMOVAL OF THE OVARY OR TUBE.

DR. HOWARD KELLY recently brought this procedure before the Johns Hopkins Medical Society.[1] In the past few years the tendency has been towards more conservative methods in disease of the uterus and appendages. Ovaries are no longer removed for enlarged Graafian follicles, and it is generally recognised that no one should remove a Graafian follicle unless it is so much enlarged as to have become a small ovarian cyst. The follicle is simply excised and the ovary sewn up. Accumulations of pus in tubes or ovaries are treated by vaginal puncture and drainage. The removal of parovarian cysts without tube or ovary is one of the latest procedures in this conservative line. Dr. Kelly's first case was that of a woman on whom he operated in November, 1895. There was one parovarian cyst the size of a hen's egg before the uterus and another behind it which displaced the ovaries from the tubes. He treated the tumours in different ways. In one, after ligaturing the vessels at a little distance from the tumour, he made an incision through the peritoneum, and easily shelled the tumour out of its bed and then sewed up the peritoneum. In the other he excised a portion of redundant peritoneum whilst the circulation was controlled by the finger of an assistant, turned the tumour out, and stitched up the wound with catgut. The uterus, which was retroflexed, was suspended by two silk sutures after his method. The patient recovered and is in good health. Dr. Kelly regards the operation as of particular importance to young women and women in the prime of life.

[1] Bulletin, March, 1897.

CHARING-CROSS HOSPITAL.

WE understand that a cheque for £1000 has been received from the Sir Augustus Harris Memorial Committee, through the treasurer, Mr. Alderman Frank Green, for the endowment in perpetuity of a bed at Charing-cross Hospital in memory of the late Sir Augustus Harris. The bed is very properly to be reserved for patients connected with the dramatic, musical, and music-hall professions.

MANIACAL CHOREA IN A MALE.

IN the last number of the *Journal of Mental Science* Dr. Thomas P. Cowen relates a case of an interesting and somewhat unusual character. The patient was a man aged twenty-one years, who had shown no symptoms of mental disorder until a fortnight before his admission to the asylum. His natural dull reticence then became more distinct, and at the end of a week a well-marked condition of mental stupor resulted. Four days later he emerged from this condition, becoming acutely maniacal, shouting and raving incoherently, and presenting the usual tendencies to destructiveness and impulsiveness. On admission to the asylum there was no obvious sign of nervous disease and his bodily organs were found to be healthy. There was no tremor or abnormal movement and the reflexes were present. He could give no coherent account of himself, and he was dirty in his habits. During the first month of his time in the asylum he remained acutely maniacal, but about the end of this time choreiform movements were visible in the hands and in the facial muscles. These became gradually more marked, and as they did so the mental symptoms became less distinct and obtrusive. There was no pyrexia, and no evidence of cardiac disease was discovered. In the course of the next month the spasms became much less marked, but there was a fresh temporary outbreak of the maniacal excitement. This soon disappeared and his general condition rapidly improved, so that in less than four months after his admission he was practically well. No cardiac complication developed during the attack. The writer points out that the interest of the case consists in the occurrence of the condition in a male adolescent (*chorea insaniens* being described as occurring as a rule in women), the precedence of the attack of typical chorea by mania, the absence of pyrexia, and the rapid recovery after the cessation of the movements.

THE HOUSING OF COWS.

NOTHING has been more clearly established than that milk is frequently an important factor in the transmission of disease, and this emphasises the extreme importance of providing a sanitary environment for the cow. The medical officer of health of Manchester has recently presented an interesting report on this subject, and the necessity of making inquiry in this direction is evident from the summary of his results. He found:—1. The state of the cow-sheds bad as regards crowding, ventilation, and lighting. The floors also are often bad. 2. The cows are not infrequently dirty. 3. The milk in a considerable proportion of selected instances has been shown to be highly dangerous, to young children especially. Dr. Niven points out as a moral reminder that steps have been taken elsewhere as in London, Liverpool, Glasgow,

Hosted by Google

Edinburgh, and Sheffield, to deal with these conditions. Attached to the report are the results of an interesting bacteriological investigation by Professor Délepine. The conclusions arrived at are in strong confirmation of the views already held by many well-known authorities. These are as follows:—1. That the milk of tuberculous cows of which the udder is not diseased is rarely infectious (though it must be remembered that the udder may become tuberculous at any time). 2. That in tuberculous cows, when the udder is diseased, this may be due to tuberculosis or other diseases. In half the cases examined the disease of the udder was due to tuberculosis. 3. That when the udder is tuberculous the milk is generally infectious and is a source of great danger to young children. We trust that the requirements as to cleanliness of the sheds where cows are kept will be, in view of this clear summary, rigidly enforced in every town in the kingdom.

THE MEDICAL SOCIETY OF LONDON.

THE annual conversazione of the Medical Society of London took place on May 17th, and a large and distinguished gathering of Fellows and visitors assembled to hear the annual oration, which was delivered by Mr. Edmund Owen. He chose for his subject "The Medical Society of London in the Eighteenth Century," and the address will be found in full in another part of our present issue. The orator did not adhere with too rigid pertinacity to his text, and witty and often caustic allusions to many present-day abuses were interwoven with a very graphic account of the times of Lettsom and Fothergill, drawn largely from the old minute and cash books of the early years of the society. It is to be hoped that the Council will adopt Mr. Owen's suggestion and see that these books, which contain priceless records of other times, are carefully bound, and secured in a fireproof case. The enthusiasm with which the vote of thanks was adopted showed how thoroughly the oration had been appreciated by an overflowing meeting. The subsequent Presidential reception was largely attended, and the rooms of the society were crowded till a late hour, the conversazione being one of the most successful of recent years.

A SCHEME FOR AN INTERNATIONAL LANGUAGE.

WE have received from Mr. L. Samenhof, of Grodno, Russia, a little pamphlet concerning the desirableness of there being a universal language. That this is a most desirable (if unattainable) end everyone is agreed. Mr. Samenhof mentions the efforts already made in this direction and instances two attempts, the one "Volapuk," and the other the language "Esperanto" of which he himself was the founder. The first of these languages was founded upon living tongues; the latter, so far as we remember, was a modified Latin and so a dead language. Besides these proposals there was a third made by a certain party who argued that the international language should be an entirely new one. Mr. Samenhof's idea is to have an international conference on the subject and he proposes to bring this about in the following fashion. Those interested in the subject are requested to write to him at the above address in any language they please, sending an article setting forth their views on the matter. All essays must be signed with the name of the writer and will be published in a work of 960 pages to be issued in three volumes. When the book has been published subscribers will be requested to read all the opinions and then to fill up a paper saying (1) whether they think that the universal language should be an existing language, living, dead, or "artificial," or (2) an entirely new one. We wish Mr. Samenhof every success in his well-meant efforts, but one initial difficulty that strikes us is the following — How are the subscribers to read all the essays written in languages they do not know? We English are, perhaps, the worst linguists in the world; most of us could read the French and German, some perhaps the Italian and Spanish in addition; as for Oriental tongues, although we are the greatest Oriental power, very few of us can even read Arabic, Turkish, Persian, or any of the various dialects and tongues spoken in Hindustan. We shall, however, watch with interest the result of Mr. Samenhof's experiment.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS AT MOSCOW.

GUESTS of the Congress, including ladies, will pay no admission fee, but they will not be entitled to the free railway passes from the frontier stations on the Russian lines accorded to members. They will, however, enjoy the privileges accorded by other foreign railway and navigation companies, and may take part in the excursion to the Caucasus organised by the Executive of the Congress. They will also probably be able to avail themselves of the advantages of cheap circular tickets, the arrangements for which are still under discussion. A special committee has been formed in Moscow to arrange for hotel and lodging accommodation for visitors, under the presidency of Professor Chervinsky, of Moscow, to whom applications may be made for information. Rooms may be retained in advance, and, in addition, offices will be established at each of the railway stations in Moscow, where applications may be made on arrival. The cost of rooms will average about 4*s.* 6*d.* (two roubles) per diem. A committee of ladies of Moscow has also been formed with the object of insuring the comfort and convenience of ladies belonging to the families of members of the Congress who may attend. This committee will have a central office, at which visitors on their arrival may obtain any information they require and also learn the most satisfactory way of employing their time in visiting places of interest in Moscow during the sittings of the Congress. This committee wishes to be apprised in advance of the names of all ladies who will be present, and notice should at once be given to Professor Savelieff, the secretary of the ladies' committee, through Professor W. K. Roth, the general secretary. A general prospectus of the arrangements for the Congress will shortly be ready and will be obtainable on application to Professor W. K. Roth, Secretary-General, Twelfth International Medical Congress, Moscow.

THOSE who were privileged to hear the maiden speech of Lord Lister in the House of Lords report that he made a very good beginning. He spoke without undue nervousness, was well received by the House and well dealt with by the reporters. It is a new sphere for medical men; but the result is such as to justify their translation in yet greater numbers.

H.R.H. THE DUKE OF CAMBRIDGE, who is next in seniority to Mr. Gladstone as a Governor of Guy's Hospital, has intimated his intention of taking part in the reception of H R H. the Prince of Wales on the occasion of the Royal visit to open the New Medical School Buildings on the 26th inst.

H.R H. THE PRINCE OF WALES'S first visit to Cheltenham, which occurred last week, passed off in every way most satisfactorily, no little credit being due to the efforts of the reception committee, the chairman of which, Mr. Ward-Humphreys, M R.C.S. Eng., L.R C.P. Lond., had the honour of being introduced to His Royal Highness.

THE annual dinner of old students of King's College, London, will be held at the Holborn Restaurant, on Monday,

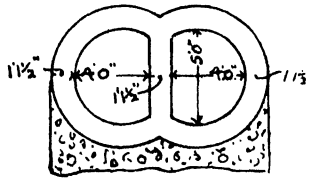
Hosted by Google

June 28th. Lord Kelvin will preside, and H.R.H. the Duke of Cambridge, has intimated his intention of being present.

PRINCESS CHRISTIAN, the President of the newly formed Army Nursing Service Reserve, upon May 19th presented badges and certificates to fifty enrolled nurses at the United Service Institution.

THE University of Toronto has decided to confer the degree of LL.D. upon Lord Lister, Lord Kelvin, Lord Rayleigh, and Sir John Evans.

The Lancet Special Commission ON THE METROPOLITAN WATER-SUPPLY.



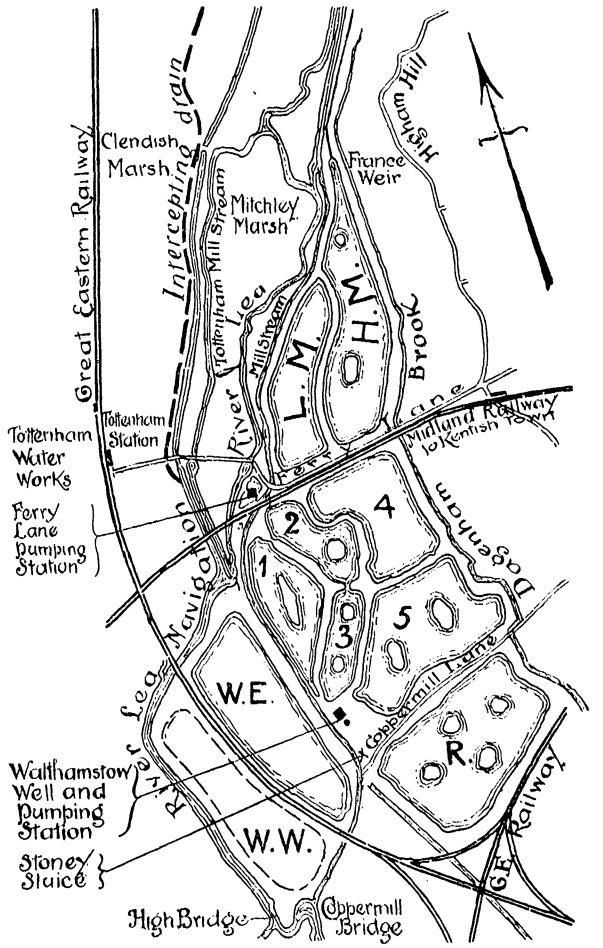
XIII.[1]

EAST LONDON WATERWORKS COMPANY (*Continued*).

Conveyance of water from Chingford to Walthamstow.—The high level culvert derives its water from the east side of the artificial cut which was formerly the mill head of Chingford mill. The low level aqueduct was formerly the Chingford mill tail; it is an open stream throughout the whole of its course. The water which flows down it is always principally, and often entirely, supplied from the Lea, but occasionally some water is pumped into it from the well at Chingford. It supplies the low level reservoirs at Walthamstow.

The high level aqueduct.—The water taken by the high level reservoirs comes from the east bank of the canal. There is here a floating boom to keep back the weeds. The water flows into a circular bay, from which it passes through two sluices into an oval pool, which is about 160 ft in length and 80 ft. in breadth. The sides of the pool are concreted and the upper part is lined with blue Staffordshire bricks. On the east side are the openings of two D-shaped culverts. (See Fig. 1.) The water passes into the culverts

FIG. 1.



The diagram shows a section of the high level culverts. These are built of brick and bedded in concrete.

through iron gratings which have bars about ⅜ in. in thickness and 1¾ in. spaces. The culverts are built of brick and rest on a foundation of concrete. The distance from Chingford to the reservoirs at Walthamstow is about two miles, and there is an available fall of 2 ft. when the receiving reservoir is full. In the whole of its course the culvert is below the level of the ground, but there are a number of brick shafts which rise above the surface of the ground and which are connected below with the culvert. These shafts are about eight in number and are situated at pretty regular intervals. With the exception of one all the shafts are covered at the top either with paving-stones or with iron traps. The shafts facilitate the examination of the culverts, and would be of use in case it became stopped up or in any way defective. From the intake the water passes at first in a south-easterly direction under the high road, it then goes in a southerly direction across a meadow to the west of the road, and later again goes under the road at a place called Folly-lane. For the latter half of its course the culvert passes on the property of the Company, except where it crosses a public footpath near Higham Ferry. The part which runs in private ground is fenced in, and for the last half mile or so the culvert runs close to the low-level aqueduct. In its course the culvert is protected from two foul streams. Of these the first is the Ching brook, which contains the sewage effluent from the Chingford sewage farm. This brook passes under the culvert about three quarters of a mile south of the Chingford Station, it then runs for about three hundred yards between the high and low level culverts, and is finally conducted in a westerly direction under the latter by means of iron pipes, which conduct it into the River Lea below all the intakes of the Company. The Ching brook on May 2nd was a small stream, dark in colour, and of offensive smell. After heavy rains it contains much flood water, but during the summer it is nearly dry and is said to be extremely offensive. The other foul stream which is near the culvert is Dagenham brook. This arises on the slope of Higham Hill, and is polluted by a farm. It passes to the east of the Company's property, and in part forms its eastern boundary. It need only be added that after receiving much surface drainage it finally goes into the Thames at Bow Creek, and that it is under the care of specially appointed Commissioners.

Walthamstow reservoirs.—Before describing these reservoirs in detail it may be best to give a brief description of their general arrangement and situation. It will be readily seen by studying the accompanying map (Fig. 2). At the

FIG. 2.

The map shows the Reservoirs at Walthamstow. H. M., High Maynard. L. M., Low Maynard. R., Racecourse. W. E., Warwick East. W. W., the part included in the dotted line, shows the position of the Warwick West, now in course of construction.

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., and XII. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, 24th, May 1st, 8th, and 15th, 1897, respectively.

Hosted by Google

western boundary of the reservoirs will be seen the Copper Mill Stream, the river Lea, and the River Lea Navigation Cut. On the eastern side the reservoirs are bounded by Dagenham Brook. Two reservoirs are situated to the north of Ferry-lane, the High and Low Maynard (see H.M. and L.M. in map). Between Ferry-lane and Copper Mill lane are situated Reservoirs Nos. 1, 2, 3, 4, and 5. Between Copper Mill lane and the Chingford branch of the Great Eastern Railway the Racecourse Reservoir is situated (see R. on Map). The other reservoir is the Warwick East (see W.E. on Map). To the south-west of this, next to the Lea Navigation Cut, is a reservoir now in course of construction, Warwick West (W.W. on Map). These reservoirs have not the same water level. There is a series of high-level reservoirs and a series of low-level reservoirs. The high-level reservoirs are the High Maynard, Nos. 4 and 5, the Racecourse, and the Warwick East; the top water level of these reservoirs is 35·60 above ordnance datum. The low-level reservoirs are the Low Maynard and Nos. 1, 2, and 3; their top water level is 26·60 above ordnance datum.

High Maynard reservoir (see Fig. 2, H.M.).—This reservoir is supplied by a high level culvert which brings water from Chingford and opens into it at its northern extremity. It has an area of rather over thirty-six acres and is estimated as being capable of holding 150,000,000 gallons. The reservoir is surrounded by a puddle trench of clay, which goes down to the London clay. There are gravel walks all round, and the banks are covered with grass. There are two islands which are planted with trees. The sides of the reservoir have concrete walls in some places, but not all round. The walls have been put up only where the wash of the water caused by the wind has rendered it necessary to do so for the protection of the banks. Near the boundaries of the Company's property there is a belt of lime and poplar trees, and these do much to break the force of the wind. The islands were made chiefly because their formation was the readiest method of getting rid of the earth which was excavated in forming the reservoirs, but they also do much to check the ravages of the wind. They are planted with furze, lilac, lime and willows, and they add very greatly to the beauty of the place.

Reservoir No. 4 (see Fig. 2-4).—The water from the High Maynard reservoir passes to this reservoir which is situated to the south of it, and is divided from it by Ferry-lane, and by the branch of the Midland Railway which runs from Kentish Town to Tilbury. The north and east sides of this reservoir are concreted. The greatest depth is about 25 ft. As will be seen by reference to the map, the reservoir has a somewhat irregular shape and it has no island. Its area is rather over twenty-nine acres, and its capacity is stated to be 129,670,000 gallons. The water passes from No. 4 to No. 5.

Reservoir No. 5 (see Fig. 2-5).—The area of this reservoir is over thirty-nine acres, and its capacity is stated to be 170,320,000 gallons. There are two islands in it. There is a concrete wall of 6 ft. or 7 ft. in height round the bank. After passing through this reservoir the water goes either to the Racecourse reservoir or to the Warwick East reservoir, which it entirely supplies. The water is conveyed to the Warwick East through a tunnel which passes through the London clay, and which is built of brick and concreted. The culvert is of circular form 5 ft. in diameter. A brick shaft, which comes 6 ft. above the surface of the ground, passes down to this tunnel, so that when the water is pumped out it is possible to examine its whole length.

The Racecourse reservoir (see Fig. 2, R.), is situated just at the north of the Chingford and Liverpool-street branch of the Great Eastern Company's line, and is separated from No. 5 by Copper Mill lane. The area of the reservoir is fifty-nine acres, and is capable of holding 270,000,000 gallons. It has four islands. The sides of the reservoir are partly supported by a sloping concrete wall. The top of the water level is 15 10 ft. above the outlet, which opens into the aqueduct which conducts the water to Lea Bridge. At the north-west corner of the reservoir there is a brick shaft into which water could be conveyed from the ballast. In case of drought if the reservoir were empty this arrangement might be used for obtaining the last water from the ballast; for if all the water were taken from the reservoir a considerable amount of residual water would be left in the ballast above the London clay. The Racecourse reservoir is supplied with water from No. 5. Between the Racecourse reservoir and the Warwick East reservoir a meter-house is being erected to measure the water which passes to the Aqueduct to Lea Bridge.

Warwick East reservoir (see Fig. 2, W.E.).—This reservoir has only been finished about three weeks. The area of the reservoir at the top of the water level is forty-five acres. The top of the water level is 35·60 ft. above ordnance datum, and it is capable of holding 210,248,000 gallons. The puddle trench which surrounds the reservoir is some feet higher than the top water level. It is not at present proposed to store more than the amount of water given—that is to say, the reservoir will not be filled to a higher level than 35·60 ft. above ordnance datum, and, indeed, this could not be done without pumping. The puddle walls are, however, raised to such a height that it would be possible for the reservoir to be filled to a height of 38 ft. above ordnance datum.

Low Maynard reservoir (see Fig. 2, L. M.).—This is the first of the low level series of reservoirs. The water which supplies it comes from Chingford mill by the low level aqueduct. The area of the reservoir is twenty-five acres and it has a capacity of over 62,000,000 gallons. The water from this reservoir supplies Nos. 2 and 3. The inlet to the reservoir is guarded by a sluice, which is shut as soon as the water becomes turbid. This is the duty of one man, who does nothing else but that and minor gardening operations, which ensure his presence in the neighbourhood. The water passes through an iron grating of which the bars are 1 in. in thickness and the spaces 1 in. The size of the inlet is 8 ft. by 10 ft.

Reservoir No. 1 (see Fig. 2-1).—This reservoir is situated near the Ferry Lane pumping station. It has an area of a little over nineteen acres and a capacity estimated at something over 45,000,000 gallons. It has one island. The supply of water is derived from the low level culvert and is discharged into the aqueduct which goes to Lea Bridge.

Reservoirs No. 2 and No. 3 (see Fig. 2-2, 3).—These reservoirs are really continuous; the opening connecting them is a narrow strait and the two parts are separated by a peninsula. The part to the south is called No. 3, and in this part there are two islands. In the part called No. 2 there is one island. The area of No. 2 is about thirteen acres and its capacity 31,000,000 gallons, and the area of No. 3 is rather over 11 acres and its capacity 25,220,000 gallons.

From reservoirs Nos. 2 and 3 the water goes through a culvert, and some of it passes through a circular receptacle to the aqueduct which takes it to the Lea Bridge station. Into this receptacle four channels pass: one from reservoir No. 1 on the north; on the east side there is a conduit from reservoirs No. 2 and No. 3; on the west side a culvert which passes to the Coppermill stream; and on the south a conduit which passes to the aqueduct to Lea Bridge.

Aqueduct to Lea Bridge.—The water from the Walthamstow reservoirs is conducted to Lea Bridge through an open aqueduct; the distance is about a mile and a half. The banks of the stream are grass slopes and there is a gravel walk on each side. The aqueduct is fenced in throughout the whole of its course. The water taken by the aqueduct is derived from: (1) Lea water which has been allowed to subside in (*a*) the high level, and (*b*) the low level reservoirs; (2) well water from Ferry-lane; and (3) water from the well at Walthamstow. This water is all filtered at the chief pumping-station at Lea Bridge.

Ferry-lane Works (see Fig. 2).—The pumping station at Ferry-lane is situated just to the south of Ferry-lane and to the north of reservoirs No. 1 and No. 2.

Filter beds.—There are at Ferry-lane three filter beds which together occupy an area of about one acre. The walls are built of brick. The bed of the filter is constructed as follows. A layer of large stones 9 in. in thickness, above this a layer of hoggin 9 in. in depth, and at the top 2 ft. of sand. Each filter bed has one central culvert, no lateral ones. The water used to supply the filter beds is drawn from reservoir No. 4 or from the Coppermill stream. The water pumped from Ferry-lane is obtained also from the deep well at Walthamstow.

Well.—The water is pumped by a triple expansion engine which has cylinders with a diameter of 21½ in., 33 in., and 55 in. respectively, and a stroke of 3 ft. 3 in.; this works three plunger pumps each 26 in. in diameter. The quantity raised is 224 gallons at each stroke. Steam is generated by three Lancashire boilers and the engine is worked at a pressure of 135 pounds. An automatic stoker is used. The water is pumped to Hornsey Wood reservoir and to Haggar-lane, Woodford. The head of water worked against in pumping to Hornsey Wood is 125 ft., and in pumping to Haggar-lane it is 176 ft. The station is lighted by electricity

Hosted by Google

which is generated by a turbine worked from the high-pressure mains.

Walthamstow Well and Pumping Station (See Fig. 2). There is a well 199 ft. in depth, which has fourteen bore holes. The water is pumped by an engine, with cylinders 27 in., 40 in., and 57 in. respectively in diameter, which has a stroke of 5 ft. and works a pump of which the bucket is 26 in. in diameter and the stroke is 5 ft. Each stroke raises 230 gallons of water. The engines work at a pressure of 95 lbs. The pump rods are worked by means of a disc. There is another engine with cylinders 24 in. and 44 in. respectively in diameter and a stroke of 6 ft. This works a pump which has a stroke of 6 ft. and buckets of which the diameters are 22½ in. The quantity of water pumped is 206 gallons per stroke. The steam for working the engines is generated by four double flue boilers of marine type. The water raised from this well flows by gravitation to Ferry-lane or to Lea Bridge through the aqueduct.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 13th, the President, Sir WILLIAM MACCORMAC, being in the chair.

The Secretary having reported the death of Mr. Walter Rivington, member of the Council, the Council expressed their deep regret at the death of their colleague, and their very sincere sympathy with the members of his family. The Council also recorded their great esteem for the energy and devotion displayed by Mr. Rivington in all matters affecting the interests of the College and the medical profession.

The President stated that the vacancy on the Council occasioned by Mr. Rivington's death would be filled up at the annual election of members of the Council in July next.

The following resolution was carried:—

"That the Council hereby express their deep regret at the death of Mr. James Blake Bailey, and their very sincere sympathy with Mrs. Bailey in her bereavement. The Council do also record their great appreciation of the very able manner in which Mr. Bailey during the past ten years fulfilled the duties pertaining to the office of librarian, and are assured that his unfailing courtesy and willingness to render assistance to all seeking information from the books and records under his care will cause his loss to be widely felt throughout the profession."

It was referred to the Library Committee to consider and report to the Council upon the steps to be taken with the object of filling up the vacant office of librarian.

Mr. W. A. Meredith was introduced and was admitted a Fellow of the College under the rules applying to the election to the Fellowship of Members of twenty years' standing.

Mr. Robert Cozens Bailey, F.R.C.S., was introduced, and was handed the Jacksonian Prize.

The following address of congratulation to the Queen was carried unanimously:—

THE HUMBLE ADDRESS OF THE PRESIDENT, VICE-PRESIDENTS, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

TO

HER MOST EXCELLENT MAJESTY

VICTORIA,

QUEEN OF GREAT BRITAIN AND IRELAND.

MAY IT PLEASE YOUR MAJESTY,—

We, the President, Vice-Presidents, and Council of the Royal College of Surgeons of England, humbly desire to express to Your Majesty, in this the sixtieth year of Your Majesty's Reign, our grateful sense of the blessings enjoyed under Your Majesty's wise and beneficent rule.

We also desire to record our grateful recognition of the many and great advantages that have been secured by Science, by the Arts, and by Legislation during the past sixty years, and we venture to think that not least among these may be reckoned the progress which has been made in the Science and Art of Surgery, for the promotion of which this College was founded.

But we are conscious that, however much the happiness of Your Majesty's subjects may be due to the general advancement of knowledge, very much also is due to the great personal influence for good which Your Majesty never fails to exercise on all occasions affecting the welfare of this country and people, and we pray that Your Majesty may long be spared to reign over us, and that we may continue to be blessed by Your Majesty's life and example.

In witness whereof We, Your Majesty's loyal and dutiful subjects, have caused the Common Seal of the College to be hereunto affixed this 13th day of May, 1897.

The Museum Committee recommended, and the Council appointed, Mr. S. George Shattock, F.R.C.S., as Pathological Curator of the Museum, the appointment to date from next Midsummer.

"Hydrophobia" was selected as the subject for the Jacksonian Prize for the year 1898.

The consideration of the report from the committee on the Norwich Memorial and Medical Aid Associations was postponed.

The annual meeting of Fellows of the College for the election of members of the Council was appointed for Thursday, July 1st, at 1.30 P.M., and the meeting of Fellows was appointed for the same day at 5 o'clock P.M.

A memorial was read, which had been signed by thirty-two Fellows and Members practising in and about Plymouth, Devonport, and Stonehouse, in favour of Mr. R. B. Anderson's application for protection under Section 15 of the By-laws and of a contribution from the funds of the College towards the objects of his defence, and asking the Council if they should not favour the view entertained in the memorial, to hear them by deputation in support of Mr. Anderson's application.

It was resolved that they should be informed that the Council were unable to accede to the request.

A memorial was read, which was signed by twenty-seven Fellows and Members of the College practising in and about Plymouth, Devonport, and Stonehouse, asking whether the Council, on the submission of proper evidence, would be prepared to restrain Fellows and Members of the College by means of the disciplinary powers provided by the By-laws from practising as medical officers of medical aid associations under certain conditions specified in the memorial, and asking the advice of the Council in reference to a resolution adopted by the memorialists on the subject of their relations with the medical officers of the "Three Towns Friendly Societies Medical Institution." It was resolved that the memorialists should be informed that the matter was still under consideration.

A letter was read from the Earl of Stamford, dated May 6th, asking the Council to contribute, either in their corporate capacity or otherwise, the sum of £30 or any larger sum to the payment of the debt of £150 incurred by the Civil Rights Defence Committee. The Council, in reply, declined to contribute anything from College funds.

THE GRECO-TURKISH WAR.

THOSE of our readers who have kept themselves *au courant* with the march of events will have learned already of the success of the Turks in driving back the right wing of the Greek army at Domoko after fierce fighting and of the retreat of the Crown Prince from that no longer tenable position. Hostilities are now suspended, and there is, we hope and believe, every prospect of an end to this unequal and lamentable struggle. Greece has paid a heavy penalty for her grave mistake and vanity in having entered on this war, and she has only added to her difficulties by her late advance in Epirus; still, it must be borne in mind that the war was the outcome of Turkish oppression and misrule in the past. Greece is not only prostrate, but she has unfortunately injured and retarded the progress of civilisation and good government in Europe. Turkey has apparently taken the bit between her teeth and her great military successes have led the Porte to make arrogant claims. Happily for the cause of peace and progress, the European Powers acting in concert are still masters of the situation, and in a position to protect Greece against exorbitant claims and a purely aggressive policy on the part of her strong and successful opponent. Edhem Pasha has, without doubt, conducted the campaign in a masterly way; having carefully matured his plan of operations beforehand, he has slowly but surely pursued it to a successful issue. We do not know how far military had to yield to political considerations, but had Edhem Pasha energetically followed up his successes he might probably have even reached Athens itself. We shall learn hereafter what were the medical arrangements on the part of the two belligerents. Those of the Turks are generally reported as having been good, but they have never been exposed to the great strain to which an unsuccessful and retreating army must necessarily be

Hosted by Google

subjected. The nature of the country and the extended sphere of military operations in which the troops of both armies were engaged have probably thrown greater difficulties in the way of medical, hospital, and transport administration than the number of wounded, for the losses in various engagements in the field do not seem to have been very great, although the sum total was probably large. What the amount of sickness has been we can only surmise. The sufferings on the part of the Greek army and of the civil population, especially within the sphere of warfare, must have been considerable.

The Sultan has ordered two hospitals, one with 600 beds and the other with 100 beds, to be built near Yildiz Kiosk, since His Majesty desires to have the men wounded in the war under his eyes.

THE ROYAL SOCIETY CONVERSAZIONE.

FROM the point of view of display the annual exhibit of the Royal Society on Wednesday was decidedly dull There was, however, no lack of material for scientific thought. The exhibits, in fact, were of a scientific rather than of a popular or sensational kind. The new process (Dansac-Chassagne) of producing photographs in colour, about which so much incredulity has been expressed, was illustrated in a series of prints in the various stages of treatment by Sir H. Trueman Wood. The details of the method are not known. In regard to recent work with the x rays Mr. A. A. C. Swinton showed his new focus tubes, in which the distance between the cathode and anti-cathode may be adjusted so as to enable the production of rays of a maximum penetrative value. The new tube was described at length in THE LANCET of May 8th. An interesting application of the x rays was shown in the exhibit of Mr. Heycock and Mr. Neville. The x rays had been allowed to pass through a sodium gold alloy, the resulting photographs showing separately the crystals of gold (opaque) and of sodium (transparent) existing in the alloys which otherwise appear to be homogeneous. Interesting results of the application of photography were shown in a somewhat similar line of research by Professor Roberts-Austen, who by means of a microscope and camera and a highly magnifying apparatus demonstrated the existence of minute diamonds (carbon crystals) in steel. A most instructive series of photographs was shown by Professor Norman Lockyer, the diagrams affording abundant testimony of the value of the spectroscope and photography in enabling a simple classification of the stars to be made based upon their ascertained chemical composition. Close by were some magnificent photographs of the moon exhibited by the Astronomer Royal. M. Guillaume performed a simple experiment showing the practically non-dilatable character of nickel steel on heating; its application to pendulums is thus suggested. The diffraction kaleidoscope exhibited by Mr. C. P. Butler is a pretty modification of the ordinary instrument. Instead of providing various coloured glasses the pure spectrum of white light is employed, the pure colours being reflected at a great number of angles with a very entertaining and pretty effect. The Marine Biological Association's exhibit was of more than ordinary interest, the chief subject of attraction being certain marine animals illustrating "commensalism," a term used to indicate the constant association of animals with one another often for mutual advantages. They are not, however, "parasites." Thus, for example, an anemone for convenience of transport often fixes itself on the whelk shell of the hermit crab, and when the crab obtains food bends down so that its mouth is brought immediately under that of the crab, the anemone thus securing what the crab lets fall. Similarly, a worm frequently dwells in the upper galleries of the whelk shell, descending from time to time to take from the crab such food as it requires. Professor Oliver Lodge gave a very interesting demonstration of Zeeman's discovery of the broadening of spectrum lines by the action of a magnetic field on the source of light. A sodium flame was placed between the terminals of a powerful magnet. On turning on the current the normal bands become double, triple, or even quadruple. The experiment is of exceeding interest in regard to the relations of magnetism and light. Some excellently mounted preparations shown by Dr. Kanthack illustrated the mode of action of the Tsetse fly. As is well known, this fly creates a scourge by communicating the micro-organisms from infected to healthy animals. The disease is due, as was shown by Surgeon-Major Bruce, to the presence in the blood and serous fluids of a parasitic protozoon. In the secretary's room the chief exhibits of interest were a telegraphic type-writer and an instrument for controlling the electric arc light in its application to photomicography. Lastly, demonstrations were given in the lantern room by Professor Ayrton and Professor Farmer, the latter illustrating "Nuclear Division in Animal and Vegetable Cells," and the former "Some Electric and Mechanical Analogues."

The President (Lord Lister) received the Fellows and their friends, and there was a large company present.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary meeting of the Comitia of Fellows was held on the 13th inst., Dr. WILKS, President, in the chair. Dr. J. A. Coutts, Dr. J. Galloway, Dr. W. Essex Wynter, Dr. W. S. Colman, Dr. A. F. Voelcker, Dr. J. Taylor, Dr. G. Schorstein, Dr. E. H. Starling, Dr. J. S. Risien Russell, Dr. A. A. Kanthack, and Dr. J. R. Bradford were admitted to the Fellowship of the College.

The President was authorised to attach the seal of the College to a loyal address to Her Majesty the Queen on the completion of the sixtieth year of her reign.

A memorial was read from the members of the Hospital Reform Association and others, with especial reference to the abuse of out-patient medical relief, asking the College to investigate the subject and suggesting remedies. A discussion took place, in the course of which it was contended by some that the matter was one which did not come under the purview of the College, but it was eventually agreed to refer the memorial to the Council for consideration.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6332 births and 3469 deaths were registered during the week ending May 15th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 18·8 to 17·0 per 1000, further fell last week to 16·5. The lowest rates in these towns were 10·4 in Swansea, 11·3 in Huddersfield, 11·6 in Croydon, and 12·0 in Brighton and in Leicester; the highest rates were 21·2 in Derby and in Liverpool, 22·0 in Sunderland, 22·3 in Manchester, and 23·0 in Salford. The 3469 deaths included 340 which were referred to the principal zymotic diseases, against 350 and 315 in the two preceding weeks; of these, 102 resulted from whooping-cough, 96 from measles, 56 from diphtheria, 32 from scarlet fever, 32 from diarrhœa, and 22 from "fever" (principally enteric). No death from any of these diseases was recorded last week in Norwich, in Huddersfield, or in Gateshead; in the other towns they caused the highest death-rates in Sunderland, Manchester, Burnley, and Salford. The greatest mortality from measles occurred in Sunderland, Bolton, Burnley, Manchester, and Salford; and from whooping-cough in Sunderland, Blackburn, Oldham, Burnley, and Plymouth. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 56 deaths from diphtheria included 42 in London and 2 each in West Ham, Cardiff, Birmingham, Liverpool, and Sheffield. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns. There were 15 small-pox patients under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 15th inst., against 7, 12, and 11, at the end of the three preceding weeks; 6 new cases were admitted during the week, against 6 and 3 in the two preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2416, against 2442, 2380, and 2385 on the three preceding Saturdays; 239 new cases were admitted during

Hosted by Google

the week, against 269, 223, and 231 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 273 and 232 in the two preceding weeks, further fell to 198 last week, and were 126 below the corrected average. The causes of 54, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Bradford, Leeds, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Sheffield, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the three preceding weeks from 22·6 to 20·7 per 1000, rose again to 20 8 during the week ending May 15th, and was 4·3 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Perth and 16 6 in Aberdeen to 21·4 in Leith and in Glasgow, and 23·7 in Edinburgh. The 620 deaths in these towns included 41 which were referred to measles, 29 to whooping-cough, 20 to diarrhœa, 6 to scarlet fever, 5 to diphtheria, and 1 to "fever." In all, 102 deaths resulted from these principal zymotic diseases, against 127 and 93 in the two preceding weeks. These 102 deaths were equal to an annual rate of 3·4 per 1000, which exceeded by 1·8 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 52 and 29 in the two preceding weeks, rose again last week to 41, and included 21 in Edinburgh, 16 in Glasgow, and 4 in Leith. The deaths referred to whooping-cough, which had been 45 to 34 in the two preceding weeks, further declined to 29 last week, of which 13 occurred in Edinburgh, 12 in Glasgow, and 3 in Leith. The 6 fatal cases of scarlet fever exceeded the number recorded in any recent week, and included 4 in Glasgow. The deaths from diphtheria, which had been 6 in each of the two preceding weeks, were 5 last week, of which 4 occurred in Glasgow. The deaths refered to diseases of the respiratory organs in these towns, which had been 128 and 134 in the two preceding weeks, declined again to 108 last week, and were slghtly below the number in the corresponding period of last year. The causes of 41, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·5 and 33·7 per 1000 in the two preceding weeks, declined again to 28·3 during the week ending May 15th. During the past six weeks of the current quarter the death-rate in the city has averaged 31·6 per 1000, the rate during the same period being 16·6 in London and 26·5 in Edinburgh. The 190 deaths registered in Dublin during the week under notice showed a decline of 36 from the number in the preceding week, and included 19 which were referred to the principal zymotic diseases, against numbers declining from 41 to 35 in the three preceding weeks; of these, 6 resulted from measles, 6 from whooping-cough, 3 from scarlet fever, 2 from "fever," 1 from diphtheria, and 1 from diarrhœa. These 19 deaths were equal to an annual rate of 2·8 per 1000, the zymotic death-rate during the same period being 1·5 in London and 6·2 in Edinburgh. The fatal cases of measles, which had declined from 19 to 8 in the three preceding weeks, further fell to 6 last week. The deaths referred to whooping-cough, which had been 13 and 16 in the three preceding weeks, declined again to 6 last week. The 3 fatal cases of scarlet fever were within one of the number registered in the preceding week, and the mortality from diphtheria and from enteric fever also showed a decline from that recorded in the previous week. The 190 deaths in Dublin last week included 30 of infants under one year of age and 48 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons exceeded those recorded in the preceding week. Eleven inquest cases and 10 deaths from violence were registered; and 62, or nearly a third, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN R. H. HALL has been ordered to the Curragh and Brigade-Surgeon-Lieutenant-Colonel Martin to Aldershot for duty. Surgeon-Major S. F. Lougheed has joined at Woolwich. Surgeon-Captain R. C. Cottell has embarked on the transport *Dilwara* for Natal. Surgeon-Major White has been transferred to the South-Eastern District for duty. Brigade-Surgeon-Lieutenant-Colonel Keys has been ordered to Belfast for duty. Surgeon-Captain S. G. Moores has been appointed as an attached medical officer to the Scots Guards.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Colonel Hendley, C.I E., Officiating Inspector-General of Civil Hospitals, North-Western Provinces and Oudh, are replaced at the disposal of the Foreign Department. The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Bombay for employment on plague duty:—Surgeon-Captain M. Boyle, A.M.S , and Surgeon-Captain E. S. Clark, A.M.S. The services of Surgeon-Captain L. Rogers (Bengal) are replaced at the disposal of the Military Department. The services of Surgeon-Captain Browning, A.M.S., are placed temporarily at the disposal of the Foreign Department for employment on plague duty. The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Bombay for employment on plague duty:—Surgeon-Captain Cleveland, Surgeon-Captain Bray, A.M.S., Surgeon-Captain Taylor, A.M.S., and Surgeon-Captain Rivers, A.M.S.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeons: Arthur W. Russell to the *Mars* and Evelyn R. H. Pollard to the *Renown*. Staff Surgeons: Thomas E. H. Williams to the *Jupiter;* Arthur W. May to the *Empress of India;* James C. Dow to the *Powerful;* John Ottley and Richard E. Biddulph to the *Royal Sovereign;* Charles W. Buchanan-Hamilton to the *Monarch*, additional, for Ascension Hospital; and John P. J. Coolican to the *Wildfire*, additional, for the *Sans Pareil*. Surgeons: George H. Foott to Haslar Hospital; Richard A. Ross to the *Jupiter;* Harold Huskinson to the *Empress of India;* John F. Hall to the *Mars;* Charles M. Beadnell to the *Powerful;* and Arthur R. H. Skey to the *Alexandria*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major George Hastings, having resigned his Volunteer appointment, ceases to be an officer of the Army Medical Reserve.

VOLUNTEER CORPS.

Artillery: 1st Glamorganshire: Surgeon-Lieutenant D. R. Bowen resigns his commission. *Rifle:* 1st Volunteer Battalion the Gordon Highlanders: Surgeon-Lieutenant G. Williamson to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Aberdeen Company: Surgeon-Captain A. MacGregor resigns his commission.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the under-mentioned officers of the Volunteer Force:—*North-Eastern District: Engineers:* 2nd West Riding of Yorkshire (Leeds) Royal Engineers (Volunteers): Surgeon-Major Charles Richardson, retired. *North-Western District: Rifle:* 5th Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant-Colonel William Richard Dambrill-Davies. *Eastern District: Rifle:* 2nd Volunteer Battalion the Essex Regiment: Brigade-Surgeon-Lieutenant-Colonel Ebenezer Shedd. *South-Eastern District: Rifle:* 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant Giles Lockwood L. Hawken, retired. *Home District: Volunteer Medical Staff Corps:* The London Companies: Surgeon-Major John Edward Squire, M.D. *Scottish District: Rifle:* 1st Lanarkshire Volunteer Rifle Corps: Surgeon-Major James Alexander Adams, M.D.; 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant Robert Grant.

THE NEW ARMY ORDERS.

The new issue of the Army List contains the announcement

Hosted by Google

of two important concessions to the Army Medical Staff. One of these concessions also affects all departmental officers. The following are the announcements:—1. Army Medical Staff.—Mess allowance to officers attached to Militia Units: "This allowance will also be granted on the same conditions to officers of the Army Medical Staff attached to a militia unit during preliminary drill and training." The allowance amounts to 4s. a day. 2. Precedence of Departmental Officers—Presidents of Boards: The Queen's Regulations and Orders for the Army will be amended as under:—The following will be substituted for paragraphs 126 and 127 of Section VI., 126. "The officer assembling a court of inquiry, committee, or board will appoint a president by name, or, failing such appointment, the senior member will preside." "When the convening officer has so appointed a president no officer senior in rank to the president will be detailed to serve as a member of the court of inquiry, committee, or board." In the second order we see a loophole for the military authorities to stultify what appears to be a move in the right direction. We hope, however, that the order is not merely a giving with one hand and a taking away with the other, and that it is not intended only as a paper concession to satisfy the public.

THE NEW REGULATIONS FOR NAVAL CADETS.

As the sons of medical officers of the Navy and Army are often desirous of entering these services, it may be well to call attention to the new Regulations respecting naval cadets which are to come into force for the examination to be held in December next. The appointments to naval cadetships, with certain exceptions that are enumerated, will be by competition, the examinations being conducted by the Civil Service Commissioners. Candidates must not be below fourteen or above fifteen and a half years of age at the date of entry, and they must be in good health and free from any physical defect. The payment on board the *Britannia* will be at the rate of £71 per annum, the Lords of the Admiralty reserving to themselves the power of selecting a certain number of cadets for whom the annual rate of payment will be £40. The alteration that has been made in respect of the increased age of candidates for cadetships is intended to encourage the admission of lads direct from public schools, but it is questionable whether it will altogether effect this, for, as the headmaster of Harrow points out, boys do not usually proceed to public schools till they are about fourteen years of age, and there is consequently not much time left for their preparatory education at such institutions.

ENTERIC FEVER IN INDIA.

It is at this season and in that succeeding the rains in India that enteric fever so often prevails. The total number of cases that have occurred in the Black Watch at Subathu is fourteen. The patients under treatment are doing well. Brigadier-General Symons has proceeded to Subathu to inquire into the cause of the outbreak, with authority to take whatever measures may seem desirable. Some cases of enteric fever have also occurred at Agra among the men of the York and Lancaster Regiment. If the medical history of Subathu be inquired into it will, we believe, be found that it has proved an unhealthy station, and that for many years past there have been occasional outbreaks of enteric fever there.

ARMY MEDICAL SCHOOL, NETLEY.

It is now definitely decided that Deputy-Surgeon-General Henry Cayley, I.M.S. (retired pay), will retire from his appointment as Professor of Military Medicine in the Army Medical School at Netley on July 31st.

Surgeon-Major-General Cleghorn, Director-General of the Indian Medical Service, has arrived at headquarters, Simla, relieving Surgeon-Colonel Warburton, who has returned to his post in the North-Western Provinces.

KING'S COLLEGE HOSPITAL.—The annual dinner in aid of the funds of King's College Hospital was held at the Hôtel Métropole on May 15th. Lord Glenesk, who was in the chair, said that the Prince of Wales's Hospital Fund would no doubt be of great assistance to them; they would, however, none the less rely on the liberality of their ordinary supporters. Subscriptions and donations amounting to £2760 were announced in the room, including £250 from Lord Glenesk, £500 from Messrs. W. H. Smith and Sons, and £100 from Mr. W. F. Smith, M.P.

Correspondence.

"Audi alteram partem."

"THE DECLINE OF THE SCOTTISH UNIVERSITIES."

To the Editors of THE LANCET.

SIRS,—If you think it worth while to continue the discussion on the decadence of the Scottish universities I would like as a graduate of one of them, and as having bestowed some consideration on this subject, to add a very few words. Before doing so I wish to say that I agree with almost every sentiment in the able and trenchant letter of Dr. McVail in THE LANCET of May 8th. No doubt, also, as Dr. Milroy remarks, the introduction of the five years' system has had a decided effect, as has the increased—nay, excessive—stringency of the preliminary medical examinations, in reducing the number of entrants. I wish I could believe that the manifest overcrowding of the profession has as yet told to any appreciable extent on the young men seeking admission. But I suspect he is wrong as to the comparative falling off in arts and medicine. I rather think the falling off is most marked in arts students, and with your leave I wish to state very shortly why this is so. A commission has been now sitting for many years and has published many—too many—ordinances regulating the courses of study in our Scotch universities. It has been a cumbrous and weak body. On the one hand, it has been afraid to touch the time-honoured fabric of old-world education, and, on the other hand, it has opened the doors wide to a heterogeneous assortment of studies. A student may at his own sweet will take his classes in at least one hundred different ways. The real prizes—what are known as bursaries—are given on the old lines of Latin and Greek, with a little English mathematics thrown in, while modern languages are nowhere. Can it be wondered that parents doubt the good of all this jumbling and bungling and do not send their sons to waste their precious time on so ill-considered a hash of subjects?

Let the Scottish universities march with the times. Put modern languages at least on a par with dead tongues as instruments of culture; try to encourage science of the right kind; but, above all, let there be a director of studies—why not the principal?—whose duty it will be to examine each student systematically and carefully and to advise the parents and guardians of pupils what would be the course of study best suited for each individual case. Scottish students have benefited greatly by their independence of tutors and masters; but license is something more than liberty, and a few words spoken wisely and sympathetically may change (and has changed) the whole current of a young man's life and character into higher and nobler channels.

I am, Sirs, yours truly,

May 9th, 1897. WILLIAM BRUCE.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—Dr. G. Archdall Reid has strangely misunderstood me, and has consequently been led to tell me many things which I knew quite well and never questioned. The acquirement of language is a twofold process, comprising what may be termed a *receptive* and an *expressive* side. If he will read my letter again he will see that I was clearly speaking of the expressive side of the process only. The case I cited was that of a boy whose hearing and mental powers were good, in whom consequently language on its receptive side could be acquired in the usual manner. The use of the expressive side, however, was altogether deferred till after the fifth year, and then, when his nervous system was more matured, he suddenly spoke certain words quite distinctly, though there had been no previous trials and failures. This boy did not learn to speak (expressive side) in any ordinary sense of the term, and my point was that he would never have been able at once to execute all the complex muscular movements needed for the utterance of words if he had not inherited the necessary nervous arrangements by which, in part, these motor acts were brought about. The same reasoning applied to the child who walked across the room at two years of age, but

Hosted by Google

who, up to that period, had never even tried to walk. In spite of my having told him of this exceptional circumstance (upon the authority of Sir Richard Quain) Dr. Reid now complacently tells me and your readers generally that a child can only do this "through use and after long practice." The fact I have cited is certainly hostile to Dr. Reid's theories, and tends to show that when walking is delayed much beyond the usual time, such complicated motor acts may be exercised, independently of previous trials and failures, simply because in the mean time the motor mechanisms concerned with these acts which the child has inherited have had time to develop.

I am, Sirs, faithfully yours,

Manchester-square, May 17th, 1897. H. CHARLTON BASTIAN.

DR. RENTOUL AND THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—From the letter of my colleague, Dr. R. R. Rentoul, published in THE LANCET of May 15th, it would appear that he only imperfectly realises his position as a Direct Representative. Having undertaken to act as representatives of the profession on the Council it appears to me that it is incumbent upon us, at whatever personal sacrifice, to attend the meetings of the Council and to do all we can to promote the interests of our constituents. The Direct Representatives are so few in number that for one to drop out of the ranks is to weaken the influence of the others. I trust, therefore, that Dr. Rentoul will, nothwithstanding what he has said, take his seat at all the meetings during the forthcoming session of the Council.

I remain, Sirs, yours faithfully,

GEORGE BROWN,
Direct Representative for England and Wales.

Hart-street, Bloomsbury-square, W.C., May 18th, 1897.

OPHTHALMIA IN LIVERPOOL.

To the Editors of THE LANCET.

SIRS,—I am surprised to find a leading article in a journal like THE LANCET, that has for a motto "Audi alteram partem," supporting, upon what is admittedly scant evidence, the opinions of one medical man against three others.

Before replying to the leading article in detail allow me to say that I am visiting surgeon to the Liverpool Workhouse Hospital and have nothing to do with the Kirkdale or Sheffield schools and that my remarks below only apply to the workhouse. In the first place there is no question of severe ophthalmia. Mr. Fuller never used such words with reference to the workhouse. A second mistake is made at the very beginning of the article in reference to the "workhouse schools." We have no "schools" at the workhouse. The so-called "schools" are receiving or probationary wards, where children are temporarily placed until their condition and destination are accurately determined. For instance, cases of granular lids so slight as to be considered latent are sent there from the wards under medical observation to ascertain how they will do without treatment. Cases admitted from town at all hours of the day and night, apparently in good health or with such trifling complaints as not to require hospital treatment are also sent there. The "ins-and-outs" rarely get beyond this place, and its entire population is a floating one, varying in number from a dozen to fifty. Nearly every day cases are being sent to it from the wards and *vice versâ*, and every fortnight it is cleared out as far as possible, the healthy sent to Kirkdale, and the residuum to hospital or to the country homes, according to circumstances. This is the only place in the workhouse where any real fault was found by the inspector. On Nov. 25th, 1896, Mr. Fuller visited these probationary wards, which on that day contained forty-four boys and girls, and next day, on going round the ophthalmic wards, I found eleven new cases that had been sent there through Mr. Fuller's influence. I examined these cases carefully and two had absolutely nothing the matter with their eyes, one had a congested eye, and the others showed signs of having had granular lids in scars and congestions, but there were no granulations and no discharge. Some were sent back at once and others were kept for a few days under treatment, and I thought no more about the matter till February, 1897, when Mr. Fuller's report was received. Fortunately for us the state of the eyes of every case that passes through the ophthalmic wards is recorded, and I was thus able to join issue with him to the effect that his diagnosis was incorrect and that he had exaggerated the symptoms. Had it been otherwise we would have been helpless, for when his report came down only two cases out of the eleven were under the care of the vestry and the habitation of the others was quite unknown.

Now it was, with these doubtful cases in my mind, that I put the question to Mr. Fuller as to the value of the absence of discharge as a diagnostic sign of the latency of granular lids and of the danger of contagion, and, in fact, as a sign of the temporary cure of the cases. I agree that it takes years often to ensure that a permanent cure has been effected. Mr. Fuller's reply was that granular lids were always contagious in all stages, because when there was no apparent discharge the lids were found sticking together in the morning, so that there really was discharge. This sticking together of the lids in the morning would to me be evidence of discharge, and I always ask the nurse in such cases whether the children wake up with their eyes bright and clear and free from stickiness; and this is my most important sign that the disease is latent and that active treatment should stop. I have not heard Mr. Fuller's opinion as to this condition. Bacteriology may help us in the future, but the importation of the gonococcus into the discussion seems to me to show that we know very little about this phase of the question as yet and may leave it on one side. And now allow me to enlighten the writer of the leading article about the authorities quoted by me.

Mr. Nettleship says in his "Diseases of the Eye," p. 968, where he is writing of chronic granular disease, "When accompanied by discharge the disease is contagious, otherwise not." Is not that explicit? Mr. Swanzy, in his "Handbook of Diseases of the Eye," p. 87, says in reference to acute and chronic granular ophthalmia, "Both forms are contagious, and probably the infection occurs only by transference of the secretion from one eye to the other by means of fingers, towels, handkerchiefs," &c. If the writer of your leading article will go through all the other authorities within his reach he will find that they are of opinion that the discharge of the eyes is the chief factor in spreading the infection, and consequently the less the discharge or secretion the less danger of infection. I think all of us will agree that distinct granulations should be treated and isolated, whether there is apparent discharge or not; but it is in the intermediate cases between healthy lids and distinct disease where disagreement will be found. For instance, before the Poor-law Schools Committee one medical inspector said that 90 per cent. of pauper children had "unhealthy eyes"; and another examiner will find 30 per cent.; another, perhaps, 20 per cent. of unhealthy eyes in the same school. At Liverpool we adopt a common-sense and practical view of the matter—neither an ultra-scientific nor a faddist one. We have separate wards for acute and chronic cases, and convalescent homes for those convalescent. Our supply of granular lids comes to us from town and affects mostly the younger children. As the children grow older the disease disappears, and only some of the "ins-and-outs" present any injury to the eyes. We cannot quite understand the reports of frequent serious eye disease in granular lids that come to us from the metropolis, and half suspected these to be due to nimia diligentia medicorum.

The small lecture at the end of the article on granular ophthalmia is, I assure the writer, not necessary. I know all about eversion of the lids, follicular conjunctivitis, towels, damp soil, &c., for have we not read it before? and although not an oculist, my experience of granular lids exceeds that of most ophthalmic surgeons of my day, and I have always looked the disease fairly and squarely in the face. I therefore repeat that complete absence of discharge, with, of course, the unavoidable concurrent subsidence of other symptoms and signs, is one of the best practical tests of latency or cure of granular lids, and a sign that active and severe treatment should give place to freedom, fresh air, or school, provided that care and medical supervision is still exercised to detect relapse.

I am, Sirs, your obedient servant,

May 16th, 1897. W. ALEXANDER, F.R.C.S. Eng.

"VAGINAL DOUCHING."

To the Editors of THE LANCET.

SIRS,—Having to deal with many cases of gonorrhœa, I should like to make two brief comments on Dr. Giles's paper in THE LANCET of May 15th.

Hosted by Google

In the first place vaginal douching with any drug whatsoever is bad treatment for purulent vaginitis, simply because the solution cannot come in contact with the whole of the diseased surface; and if the patient douches herself, only the lower half of the vagina is douched. The best treatment is the wool tampon method; pledgets of wool, soaked in the drug it is wished to apply, are packed in the vagina through a Ferguson's speculum, and changed every day. Cases treated in this way do well if the disease has not spread to the uterine cavity.

With regard to the drugs best to use, Dr. Giles only mentions lysol and chinosol among the "new-comers." These are fairly good, but others are much better. The best in my experience, and, curiously enough, one that has not yet been advertised as a certain cure for gonorrhœa, is naphthol. I am, Sirs, yours faithfully,

London Lock Hospital, May 17th, 1897. C. F. MARSHALL.

THE CENTRAL LONDON OPHTHALMIC HOSPITAL AND THE REPORT OF THE HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—I am requested by my committee to ask you to kindly allow me space to correct the mis-statements in the above report as regards the Central London Ophthalmic Hospital. The tabular statement states:—

Subscribers' letters.—"Out-patients: Yes, about half. In-patients: Yes."—No subscribers' letters are required, and less than 2 per cent. of the out-patients come with them. The same remark applies to the in-patients, as they are admitted from the out-patients.

Payment by patients.—"Out-patients: 2*d.* a visit to 2*s.* 6*d.* per month; £426 a year. In-patients: all expected to pay 1*s.* a day; occasionally, £1 a week; £30 a year."—No charge is compulsory to out-patients, but some pay 2*d.* a visit, some 2*s.* 6*d.* a month in aid of the funds of the hospital. In the way in-patients are admitted free, but such as are able are expected to pay 1*s.* a day for their maintenance. As a matter of fact, the payment is very exceptional. Since the abolition of a private ward in 1890 no in-patient has paid more than 7*s.* per week.

Inquiry officer.—"Inquiry officer fills in forms, &c., and if he thinks proper brings the patients up to the secretary to be inquired into; has no power himself to question." "Inquiry officer only in name."—There is a proper inquiry officer, appointed in 1894, who is empowered to question patients as to their means, and who rejects those whose position does not entitle them to hospital relief.

I am, Sirs, yours faithfully,

JOHN GRIGGS BRYANT, Secretary.

Gray's-inn-road, May 17th, 1897.

"THE SUCCESSFUL TREATMENT OF A WOUND OF THE HEART."

To the Editors of THE LANCET.

SIRS,—In your Berlin Correspondent's notice of the German Surgical Association a very interesting notice of Dr. Rehn's case of wound of the heart and of his opening the pericardium is given, and without in the least wishing to detract from the credit justly due to Dr. Rehn for his bold and sound surgery I write to remind your younger readers that the opening of the pericardium, the removal of foreign bodies from it, and the washing of the sac was practised and taught by John Bell—that great surgeon who anticipated so many of our modern surgical methods.

I am, Sirs, yours truly,

Dublin, May 11th, 1897. GEORGE FOY.

URIC ACID IN THE BLOOD.

To the Editors of THE LANCET.

SIRS,—With reference to the statement of Mr. D. F. Shearer in THE LANCET of May 15th that my experiments do not appear to justify the statement that blood contains no uric acid, it is evident that Mr. Shearer does not quite appreciate the extreme delicacy of the murexide test for uric acid. Not only can half a milligramme of uric acid be detected with ease by that test, but I find that the one-hundredth part of a milligramme gives a very evident murexide reaction. Mr. Shearer has wrongly appreciated the extraction process employed by me when he refers to it as "a process in which the error of estimation is from one to two milligrammes." What I stated in my Goulstonian Lectures was that when I added known quantities of uric acid to blood I could only extract from 80 to 87 per cent. of it, so that if a given bulk of blood contained one milligramme of uric acid, the process would enable four-fifths of that milligramme to be extracted. Permit me to remind Mr. Shearer that if the uric acid contained in the urinary excretion is derived from the blood, the blood of birds should contain an abundant quantity of it, since their urinary excretion consists entirely of a compound of uric acid. As Sir Alfred Garrod originally showed, no uric acid is present in the blood of birds, an observation which was confirmed by my experiments, in which pints of birds' blood were operated upon at a time.

I am, Sirs, yours very truly,

Weymouth-street, W., May 19th, 1897. ARTHUR P. LUFF.

"POST-PARTUM HÆMORRHAGE AND ITS TREATMENT."

To the Editors of THE LANCET.

SIRS,—In his letter in THE LANCET of Jan. 16th last under the above heading Mr. E. Stanmore Bishop amongst other things indicates that he does not clearly comprehend my method of treatment as described in THE LANCET of Dec. 19th, 1896, and asserts that I speak with some doubt, &c., as to the efficacy of the procedure. I would crave of you a little space to make clear what may seem ambiguous, to show that there was little doubt in my mind, and also to make a few remarks on the position Mr. Bishop has taken up. I would state that when I wrote no one was more ready to rejoice with Mr. Bishop on his being able to point to some method of a definite nature to be pursued on being called upon to render help when a person's life is at stake—a means of freedom from, and a getting rid of, the confusion of the text-books, for I must say that with Mr. Bishop's beautiful description of the state of affairs found therein I am in the most perfect accord; but I wrote with a profound conviction that however effective in preventing the blood flow compression of the aorta may be, he was placing it entirely in the wrong position. I hope Mr. Bishop will be kind enough not to think that I wished to press his analogy too severely, and I really do not consider that I did so. I might have gone on and pointed out that in dealing with post-partum hæmorrhage we are assisting at a physiological function, but in dealing with a cut leg it is a different thing, &c., but that might have seemed unkind, and, as I thought, unnecessary. This reminds me that the simile of the plumber is also, I am sorry to say, a very unhappy one, for if a pipe is spouting and injuring valuable property a plumber is called and simply covers the aperture with his thumb instead of putty; I am inclined to think we would not consider him the kind of gentleman Mr. Bishop indicates. Now, in regard to the closing of the bloodvessels with one hand inside and the other one outside let me hasten to assure Mr. Bishop that his assumption that I meant what I said is quite correct. I meant it in all seriousness. The difficulty of compressing the two arteries and accompanying veins with the thumb need not be any annoyance to anyone, for on being reminded that uteri vary in size and condition and that men's hands are not equal in magnitude and power of grasp, and that it cannot be called a step from this to pressing one set of vessels against the pelvic wall and setting the left hand free to close the vessels of the other side—I say, on being reminded of this, we may safely assume that a moment's reflection on the great law of adaptability will settle the whole matter.

Let us look now at compression of the aorta as put forward by Mr. Bishop. As already stated, I hold he has placed it entirely in the wrong position; its fatal feature is that it does not meet the great requirement—a good working method. Let me quote his words: "From first to last, however, in every case, whether complicated by retained placental fragments, torn cervix, or any other condition, the one and only measure of primary importance in the treatment of post-partum hæmorrhage is compression of the aorta." This is a sweeping statement and requires a deal of reading. Let us see where it leads us, and let us suppose that there is

Hosted by Google

no objection to the process, such as may arise from pressure on the nerves, shutting off the blood-supply to important structures, the danger of not being able to compress the aorta above the origin of the ovarian arteries, especially when abnormally high at their origin, the difficulty, as your correspondent "Rinaldo" very properly points out, of extreme obesity, the danger of shutting the vena cava, the danger of closing the left renal vein, and that even the danger of regurgitation is absent—let us suppose these objections are all removed, and see what happens. Called to a case of bleeding, we are first of all to close the aorta, and keep it closed till the womb contracts and shuts the bloodvessels, and this too whether there are pieces of placenta present or not. Indeed, we are not to stop to find what is the cause of the bleeding. If it should be a piece of placenta, then I suppose it is to remain there, and our duty is to hold fast by the aorta. The womb is to be left to take care of itself and expel the placental fragments, clots, &c., or retain them, as the case may be—it is to fight out its own battle and strive against the difficulties nature has put in its way, and to do this in spite of the disadvantage we put it to by cutting off the blood-supply, and may I ask if it is to follow that we may then claim the gratitude of the patient for having saved her life? I would not that I should be understood to say that the aorta cannot be closed effectually, nor, indeed, should I say that it would not be a valuable method for staying post-partum hæmorrhage if a better were not at hand; but I do say that to put it forward as the first thing to be done in all cases is utterly and entirely wrong, and were this practice to be generally adopted it would lead us into following the most ridiculous and foolish procedure. It is difficult to conceive of a case where we need resort to this roundabout and rather clumsy practice — a practice which, as is shown above, requires two skilled persons to be present. Really the only case one can conceive of where this plan can claim any advantage is when there is no disinfecting material at command, and thus the only case where it may be useful is when we have unwashed hands, and even here there remains much room to doubt whether it is not inferior to the intelligent application of external pressure on the uterine surface directed so as to compress the arteries and veins as formerly described.

Regarding the important question of regurgitation I would like to say a few words, but I feel it may appear too great a presumption on my part, for if Mr. Bishop gives such short shrift to the opinions of men whose names we all revere what is likely to befall mine? However, if he will kindly accompany me for a little I will make bold enough to undertake to show that it is quite possible that these authorities may be right after all. When labour has been completed and the muscular tissue of the womb entirely fails to contract we have a condition in which there are four patent passages from the vena cava to the bleeding uterine surface except in those cases where there are valves in the ovarian veins. Should those veins be valved there remain the two uterine veins. Thus we have always at least two open channels. Now physiology tells us that the negative endocardial pressure or sucking power of the right auricle assisted by the respiratory act is about - 12 mm. to - 7 mm. of mercury in ordinary health, and let us suppose that this is reduced by weakness and loss of blood to say - 3 mm. or - 4 mm.—a little less than half. This is equal to about 0·118 inch of mercury in the first case and 0·157 inch in the latter. And if mercury be about thirteen times as heavy as blood, it means that the uterine surface requires to be from 1½ to 2 inches lower than the auricle to establish equilibrium, or in other words that the auricle, even with the help of the inspiratory suction power, is just able to prevent the blood flowing backwards towards the womb by the action of gravity; and it must be noted too that we have to grant that those flaccid and extremely feeble venous structures are able to sustain this pressure. Here, then, we have a very delicately balanced apparatus, and what is to happen when the abdominal muscles or the limbs are put in action? What can happen but blood will flow towards the open ends of the tubes, and so also should there be a frequent cough? What is to occur but that there shall be four streams carrying blood from the vena cava into the womb upon every movement of the chest? and the same must be the case with retching, vomiting, sneezing, or pressure with the hand or otherwise on the abdominal wall; each of these things must upset the equilibrium, and I should add upset it very completely too. We cannot make any pretence of assisting the heart to any appreciable degree by taking advantage of the force of gravity, for it must be borne in mind that when we raise the foot of the bed we only raise the part where the pelvis is situated by about one-half the distance which we raise the foot, and the part with which the auricle corresponds also partakes of the rise, though to a less degree; thus the assistance is extremely little, and cannot be for a moment placed in opposition to the force brought to bear on the vessels by the movement of a limb, and much less the pressure produced by a cough.

In conclusion, I would express a hope that Mr. Bishop will see his way to fall into line with me, and lend his valuable help in elucidating and making known a method suited to meet all cases, from the most trivial to the most severe, which is hardly a step removed from the routine practice of every practitioner, which comes natural to us and which we might almost call the natural method, which is immediate in its application, causes little or no pain or discomfort, and which, to put it shortly, is a good working method.

I am, Sirs, yours truly,

Heywood, Lancashire. THOMAS LAIRD.

To the Editors of THE LANCET.

SIRS,—As a reader of your most valuable journal I have been greatly interested in the controversy on the above subject, which was some time ago carried on in THE LANCET between Mr. Stanmore Bishop of Manchester and Dr. T. Laird of Heywood. Now that such a lenghtened interval has elapsed since your last published communication on the subject appeared I begin to fear the controversy has been concluded, and in so assuming I feel a keen sense of disappointment at what appears to my mind to be a premature closing of a correspondence on a matter of so high importance to all general practitioners. As one who has had an extremely limited experience among patients suffering from post-partum hæmorrhage, having been brought into contact with some three or four cases only, I feel it would be an act of great presumption to introduce myself into the arena of this debate. Still, doubtless along with many other interested young medical men, I should like to see this important question thrashed out a little more completely than it has been up to this stage, and I am yet loath to believe that Dr. Laird has said his last word on the subject; for although in his last communication Mr. Stanmore Bishop defended his own position most vigorously, his defence, even in my humble judgment, is not impregnable, nor does it bear the stamp of finality as regards the question at issue.

There is a method of arresting post-partum hæmorrhage described in the work of Dr. King, Professor of Obstretrics in the Columbian University, Washington, which has recently attracted my attention, upon the merits of which I should much esteem an expression of opinion from either of the gentlemen above named. I give the author's own words:—"A special mode of grasping the uterus—bi-manual manipulation—may be tried as follows: Press the finger-ends of the outside hand deep in between the umbilicus and the uterus, so that the latter resting in the palm may be pushed down and forward against the pubes, while the other hand (or two fingers of it), passed high up along the posterior vaginal wall, presses the lower segment of the womb—in fact, its cervix—forward towards the symphysis pubis; thus by a sort of temporary anteflexion the canal of the neck is closed and no blood can come out, while the pressure above prevents enlargement of cavity and accumulation within. It also stimulates contractions."

The foregoing method has commended itself to me all the more fascinatingly since a conversation I had on this subject a few weeks ago with a very intimate medical friend, whose obstetric experience covers over 3000 cases of labour, including fully twenty cases in which serious after-bleeding was exhibited, who stated to me that the method just described is the one he always adopts, and that he has never yet lost a case from this complication. From a theoretical point of view most of the disadvantages cited against aortic compression could not be adduced in connexion with the plan just given, whilst on the ground of the latter's practicability and efficiency the experience I have quoted greatly enhances, I think, its inherent value.

I am, Sirs, yours faithfully,

JOSEPH M. THORNLEY, M.B., C.M. Glasg.

Bolton, Lancashire, May 10th, 1897.

"PROFESSIONAL EXCLUSIVENESS IN ITALY."

To the Editors of THE LANCET.

SIRS,—I have no doubt that you are aware of an agitation which has arisen amongst some of the Italian medical men living in Rome and Florence in reference to the prohibition of foreign medical men practising in Italy without first having obtained an Italian diploma. This agitation has found expression in a circular letter sent by the President of the Accademia Medico-Fisica Fiorentina to the Italian practitioners throughout Italy. This circular states that "it has been decided to present a petition to the Minister of the Interior, in order that by legal means professional practice in Italy should be forbidden to those foreign doctors who have not an Italian degree, as is required by the other nations in Europe (Germany, Austria, France, England, &c.), in which countries not only is the national diploma required, but in some cases also citizenship." The Council of the Ordine dei Medici della Provincia di Roma have also been active in promoting this object, and they have had a special audience with the Minister of the Interior, who, it is said, gave them a favourable answer. On the 6th inst., in the Italian House of Parliament, the Under-Secretary of State, in reply to the question by Dr. Santini, one of the medical deputies, as to whether the Government did not intend to modify Article 23 of the Sanitary Law, considering the different treatment afforded to the Italian doctors who desire to practise abroad from that which Italy gives to the foreign doctors who desire to practise there, stated that the Government had already considered the question, and within a few days would place some proposals before the Superior Council of Health (now sitting in Rome), which will afterwards serve as a basis for drawing up a project of law.

This is the present position of this question which came to our knowledge on the 9th of this month. On the 10th inst. a meeting of the English medical men practising in Rome was held at the house of Dr. Charles, he being in the chair, for the purpose of considering the most desirable steps to be taken in reference to the proposed Bill to safeguard the interests, not only of the English and American medical men now practising in Italy, but also the interests of those who in the future may desire to practise in this country. It was pointed out at the meeting that the statement made in the above-mentioned circular as to foreign medical men not being allowed to practise in England was not according to the facts. On the contrary, foreign medical men can practise in the United Kingdom without restriction, but unless they are registered they cannot recover their fees by legal process, or give medical evidence in courts of law, or hold public medical offices. Moreover, under the Medical Act of 1886 the General Medical Council may recognise equivalent qualifications obtained in countries which treat the United Kingdom with reciprocity. The formalities for registration are as follows: A person who desires to be registered as a foreign practitioner must prove to the registrar that he holds a recognised foreign diploma granted in such a foreign country, and that he is of good character and entitled to practise medicine, surgery, and midwifery in such foreign country, and also that he is not a British subject, or that the diploma was not granted while he was domiciled in the United Kingdom, or was granted in course of a period not less than five years during which he was resident out of the country, or that he was practising in the United Kingdom on the said date and had been practising there or elsewhere for not less than ten years immediately preceding. He will then, on the payment of a fee not exceeding £5, be entitled to be registered without further examination. A recognised colonial or foreign diploma is one which is recognised for the time being by the General Medical Council as furnishing a sufficient guarantee of the possession of the required knowledge and skill for efficient practice, but the Privy Council have power to recognise a diploma which they have refused to recognise. In Italy, as you are aware, foreign medical men are permitted to practise only amongst foreigners unless they possess an Italian diploma, or excepting the cases in which foreign physicians and surgeons are expressly called for special cases. This is the substance of Article 23, which Dr. Santini wishes to have modified.

After a full discussion the meeting unanimously agreed: (1) that a deputation consisting of Dr. Brock and Mr. Eyre should call upon the English and American ambassadors in Rome to request their powerful support and aid; (2) that they should endeavour to obtain an audience with the Minister of the Interior for the purpose of placing the above facts before him; and (3) that they should also act for the other English and American members of the profession practising in Italy, if the audience with the Minister of the Interior was granted before these members had time to reply to this letter. The meeting, I may add, requested me to write to all the English and American practitioners in Italy, giving them an account of the above facts, and requesting their adhesion to these resolutions.

I am, Sirs, yours faithfully,

6, Via delle Finanze, Rome, May 14th, 1897. JOHN J. EYRE.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

An Unusual Case of Death from Asphyxia.

A CASE involving points of medico-legal interest was investigated by Mr. S. Brighouse, county coroner of Lancashire, at the town-hall of St. Helens, on the 4th inst. It appeared from the evidence that a Miss M. J. M'Levey, the manageress of a café at St. Helens, was found lying dead on the floor of the café at a late hour on the night of the 27th ult., a glass of water being close by. The deceased's appearance suggested that death was due to suffocation. A young man named Heath, who was paying his addresses to the deceased, was arrested on suspicion of having caused her death in consequence of having been seen near the premises on the night in question. Heath made three statements in connexion with the affair, the last statement being that he "went into the café knowing that Miss M'Levey was there putting the key in, but as soon as I got in and she heard footsteps coming in after her she turned round all of a sudden, and when she saw me she just managed to get the words out, 'Oh, how——' and then she dropped on the floor, seeming very much frightened at my appearance. Then when I saw that she had either fainted or was in a fit I did not know what to do properly. The next thing I did was to fetch some water in a glass out of the tap in the bar, but when I raised her head to give her the water I found that I could not get the water down her because of her teeth being clenched together, so when I saw that I could not apply the water down her throat I placed my fingers in the glass and sprinkled her face with it, thinking it would take effect and rouse her up. After that I raised her head again, but when I had raised it I was terrified to find water running from her mouth, but the teeth were still clenched. Then I laid her head down again, took the fur from round her neck which she was wearing, and placed it on the table, thinking that would enable her to breathe more freely. Then I raised her head again and called out, 'Maggie, speak to me.'" Heath, finding she was dead, then went home, and in the remainder of his statement said "that if anybody was to find her there I could tell them the whole truth of the matter, as she must have died from natural causes.', The post-mortem examination revealed the fact that death was due to suffocation. Dr. Rose, one of the medical witnesses, said that death was due to suffocation caused by a fit. Mr. F. Knowles agreed that death was due to suffocation, due to natural or other means. Dr. Jackson said he came to the conclusion that the girl died from asphyxia the result of an epileptic fit. He had known a case of epilepsy causing death in exactly the same manner. Mr. Challenor said that, in his opinion, the deceased first had an epileptic seizure, and his impression from hearing the evidence was that the man raised her head up and poured water down either her mouth or nose, and that produced the heart failure. If he had let the woman alone he believed she might have recovered. The jury returned a verdict of "Death from natural causes" in accordance with the medical evidence. On the following day the case again came before the magistrates at the St. Helens police-court. The charge against the prisoner was then withdrawn by the police and he was thereupon discharged from custody.

Health of Lancashire.

Mr. E. Sergeant (county medical officer of health) reported that during the three months ending March 31st the deaths recorded within the urban and rural sanitary districts of the administrative county gave a rate equal to 17·7 per 1000 of

Hosted by Google

the population, as compared with 18·3 in the previous quarter and 17·3 in the corresponding quarter of 1896.

University College, Liverpool.

The half-yearly meeting of the governors of University College, held on the 15th inst., under the presidency of Mr. William Rathbone, elicited some interesting facts. Allusion was made in the course of the proceedings to the liberality of Mr. Henry Tate, the Earl of Derby, Mr. Samuel Rathbone, Mr. William Rathbone, the late Mr. George Holt, Mr. Thompson Yates, and others. Professor Paterson (Dean of the Medical Faculty) said that several obstacles had been met with which had delayed the completion of the Thompson Yates Laboratory, which would be extremely well adapted for its purposes, as no pains had been spared to make the building complete. The formal opening of the laboratory had been postponed until next spring, when Lord Lister will perform the opening ceremony. Mr. Thompson Yates had promised two further donations—one of £6000 for providing interior fittings, and the other for providing the delicate apparatus which the department required to carry on its work efficiently. The total amount given by Mr. Thompson Yates to the laboratory was little short of £25,000. The treasurer stated that the Sustentation Fund of the College now reached £1400; to meet requirements a sustentation fund of £2000 was indispensable.

New Medical Officer at Walton Gaol.

Mr. Arthur Price, medical officer, H. M. Prison, Birmingham, has been appointed medical officer to H. M. Prison, Liverpool, in the room of Mr. George Beamish, who has been promoted to Wandsworth. Mr. Arthur Price was for five years assistant medical officer at H. M. Convict Prison, Parkhurst, Isle of Wight, prior to his appointment to the Birmingham Prison in 1887.

Hospital for Women, Shaw-street.

Dr. T. B. Grimsdale has been elected honorary acting medical officer to the above hospital, the vacancy having arisen by the retirement of Mr. J. B. Edis. Dr. Grimsdale has served on the junior staff for upwards of ten years, and is the secretary of the Liverpool Medical Institution.

Gift to the Woolton Convalescent Home.

Mrs. J. A. Willox, the wife of the Member of Parliament for the Everton division of Liverpool, has given a donation of £500 to the Liverpool Convalescent Institution, Woolton, for the endowment of a bed to be called the "Queen Victoria Commemoration Bed."

May 19th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Eye Infirmary.

THE annual meeting of this institution was held last week, the Lord Mayor presiding. Dr. Jeaffreson read the report, which showed that 3750 out-door and 250 in-door patients had been treated during the year. The income had been exceeded by £312 and the financial position of the hospital is now very serious. Dr. Jeaffreson expressed the opinion that the charity was abused, and in support of his statement instanced two cases. A man attended for six weeks with his son, and not being satisfied with the progress made by the boy proposed to bring down an ophthalmic surgeon from London at a cost of £150. The second case was that of a young man under treatment as an in-door patient in whose purse £25 was found. A good deal has been heard lately of the abuse of the Royal Infirmary from Dr. Jeaffreson, and it is to be hoped that he now sees how difficult it is to check abuse at special as well as at general hospitals.

Stockton Hospital.

Mr. Hind, who has been connected with the Stockton Hospital for some twenty years as pupil and honorary surgeon, upon resigning the latter position, was on Wednesday last elected consulting surgeon. For the vacancy caused by Mr. Hind's resignation there were two applicants, Mr. A. Dale and Mr. Rudolph Smith. Mr. Dale is a son of an old and much respected medical man in Stockton, and Mr. Smith has taken Mr. Hind's practice. Mr. Dale was elected by a large majority.

Newcastle Infirmary.

Two surgical registrars have just been appointed—Dr. Clay, the present senior resident physician, who is leaving the institution to practise in the town; and Dr. Wardale, an old student who has for some years been in practice in Newcastle.—The Building Committee has determined to adopt the principle of limited competition as the best in the choice of an architect for the new infirmary. At first it was decided to limit the competitors to the architects of Newcastle, Northumberland, and Durham, but upon further consideration it was determined that eighteen well-known architects should be asked to compete—twelve local men and six from a distance.

University of Durham College of Medicine: Heath Scholarship.

The title of the essay in connexion with the above scholarship, which was originally stated to be on "Deformities, Congenital and Acquired," has been limited to "Congenital Deformities."

Presentation to Dr. Mackay.

Dr. Mackay, of Wardley, has just been the recipient of a purse of gold as a mark of respect from his patients and friends. After the presentation he was entertained at dinner

May 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Diamond Jubilee Memorial.

A GENERAL committee of citizens of Edinburgh was formed some time ago for the purpose of raising a fund to be devoted to a permanent memorial of the Queen's Diamond Jubilee. The committee met last week and decided that a fund of £60,000 should be raised. Three schemes were before the committee—(1) a fund for the Scottish Branch of the Jubilee Institute for Nurses; (2) the establishment of a hospital for phthisical patients for Edinburgh; and (3) the erection of a special pavilion in connexion with the Royal Infirmary for the treatment of diseases peculiar to women. Each of these schemes had their claims fully laid before the meeting. The result was that one-tenth of the sum raised should be devoted to the Nursing Institute and that the remainder should be devoted to the erection of a pavilion in connexion with the Royal Infirmary for the treatment of diseases peculiar to women. The corporation of the city head the list of subscriptions with 1000 guineas.

The New Fever Hospital for Edinburgh.

At the end of last week the interesting ceremony of cutting the first turf in connexion with the erection of this hospital was performed by the wife of the Lord Provost in the presence of a large and representative gathering. A history of the work which the Public Health Committee had done in connexion with infectious diseases was given by Bailie Pollard, the energetic chairman of the committee. The cost of the new buildings, &c., will be nearly £250,000.

Appointment of an Assistant Physician to the Edinburgh Royal Infirmary.

The managers of the Edinburgh Royal Infirmary at their meeting on the 17th inst. appointed Dr. R. F. C. Leith to the vacant assistant physiciancy. There were six candidates and much interest was taken in the appointment. Dr. Leith has been for several years one of the pathologists to the infirmary.

Glasgow University.

It is intimated that the Right Honourable Joseph Chamberlain, M.P., Lord Rector of the University, has arranged with the Senatus to deliver his address to the students in the second week of November. Mr. James F. Gemmill, M.A., M.B. Glasg., has been appointed to a Lectureship on Embryology in the University. Dr. Lewis R. Sutherland has been appointed Lecturer on Pathology for the summer season. Professor Coats has so far regained his health as to be able to appear as a witness for the Crown in a case tried in Edinburgh during the current week.

Glasgow Royal Infirmary.

The annual election of the medical staff is announced for June 3rd, and it is intimated that Mr. Charles Workman, M.D. R.U.I., and Mr. R. T. Kent, F.R.C.S. Eng., have resigned their appointments as dispensary physician and assistant dispensary surgeon respectively.

Medical Appointments.

Mr. Donald Munro, M.D. Edin., has been appointed medical officer to the Weem Parish Council, Perthshire, *vice*

Hosted by Google

Mr. John Thomson, L.R.C.S. Edin., resigned. A special vote of thanks was awarded to Mr. Thomson for his long and efficient services. The position of surgeon to the Glasgow Dental Hospital is advertised as vacant. At the Glasgow Maternity Hospital there are vacancies for an indoor and outdoor house surgeon.

Medical Presentation.

Mr. John Kennedy has been presented with a handsome set of flower stands in recognition of his services as lecturer to the ambulance class organised in connexion with the goods department of the Caledonian Railway, Glasgow.

Dundee Hospital for Incurables.

The committee having for its object the erection of a Hospital for Incurables in Dundee met on the 14th inst., and received from the Lord Provost a report to the effect that there was a general feeling in favour of the scheme and that a number of subscriptions towards the £50,000 aimed at had been received. These included £10,000 from the trustees of the late Miss Thow, £2000 each from Mr. A. D. Grimmond and Miss Symers, and a similar sum from the Dundee town council.

The Diamond Jubilee and Aberdeen Hospitals.

The subscriptions to the special jubilee fund for the Royal Infirmary, Royal Hospital for Sick Children, Morningfield Hospital (Incurable Diseases), and Aberdeen District Nursing Association, now amounts to £3113 12*s*. But for recent exceptional demands on public generosity in respect of loss of life at sea and other objects the sum would have been much larger. Hospital Saturday, organised by the amalgamated friendly societies, will be on June 19th. There will be a great procession along some of the principal streets, and a popular gala in Duthie-park. It is expected to raise £1500, and arrangements will be made to prevent overlapping of the two movements.

Glasgow University Club, London.

The spring dinner of this club will take place at the Café Royal (68, Regent-street) on Friday, May 28th, at 7.30 P.M. Lord Lister will be a special guest on this occasion. Members intending to be present are requested to give immediate notice either to Mr. N. M. MacLehose, 13, Queen Anne-street, W., or to Mr. James M. Dodds, Dover House, Whitehall, S.W., hon. secs.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Nurses in the Union Hospital, Belfast.

AT the meeting of the Belfast board of guardians, held on May 1st, Dr. Bigger reported that there were 50 per cent. more cases in the hospital than there were a month ago, so that it is totally impossible for the present staff of nurses to do the work they should. During the past week 51 patients were admitted, and a large proportion of them were delirious, so that the patients cannot receive that care and attention which their condition demands. He asked for three temporary additional nurses, and the board eventually allowed three of the senior probationer nurses in the infirmary to go to the fever hospital if they wished to do so.

Typhoid Fever in Belfast.

Typhoid fever seems very prevalent in Belfast at present, and an outbreak has taken place in the Newtownbreda district. A very promising medical student died in the Royal Hospital last week from this disease.

Death of Mr. J. C. Davidson, L.R.C.P. & S. Edin.

Mr. J. C. Davidson died very suddenly at his residence, 6, Carlisle-terrace, Belfast, on May 14th. He went to bed the previous night apparently in his ordinary health, but on his sister going to awake him on the morning of the 14th she found him dead. Two medical men saw him (one of them being his next-door neighbour) at once, and came to the conclusion that his death was due to heart disease, from which it was known he had suffered, so that the coroner did not think it necessary to hold an inquest. Mr. Davidson, who was unmarried, was a young man who had for several years been in practice in Belfast, where he was much respected, and his death is very much regretted. The funeral was very largely attended.

Hospital Saturday in Belfast.

Next Saturday (May 22nd) has been appointed as Hospital Saturday, when arrangements will be carried out to make the collection for the Royal Hospital as large as possible. The fund for the new hospital amounts now to over £84,000.

Lisburn Infirmary.

At a public meeting of the inhabitants of Lisburn, held on May 17th, a resolution was unanimously passed to raise a fund commemorative of Her Majesty's Diamond Jubilee, and it was decided that the money should be applied for the benefit of the County Antrim Infirmary (in Lisburn) for the purpose of purchasing a house adjoining the present infirmary and furnishing it so as to admit a larger number of patients. Part of the money raised is for illuminations.

The Royal University of Ireland.

At the recent M.B. examinations of the Royal University of Ireland, held in May, there were sixty candidates, of whom two retired during the ordeal. When the results were declared it was found that thirty-three had passed and twenty-five were rejected; eight were placed in the upper pass division, and four were recommended to proceed to the honour examination.

The Situation at Mercer's Hospital.

Twenty-one governors of this charity met on Tuesday last, and resolved that the election to fill the vacancies caused by the dismissal of the medical staff should not take place until July 6th.

May 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Medical Men at the Paris Fire.

A SOLEMN service has been held at the Madeleine, the expenses being borne by the medical faculty of Paris, in memory of those medical men and their relations who met their death at the recent disaster in the Rue Jean-Gougon. The impressive ceremony, to which medical men alone were admitted, brought together a large crowd, so that the church was quite filled. The relatives of the victims occupied the choir, and all the officials of the Parisian Faculty were present save only the dean, M. Brouardel, who is abroad. The medical journals continue to assert that of all the men present at the fire the members of the medical profession alone did their duty. Official statistics show a tale of 121 deaths, out of which six only were males, two were children, two old men whose feebleness incapacitated them for flight, and two adults, *both medical men*—Dr. Feulard and Dr. Rochet. The former of these, having emerged, went back to try to save someone, and the latter refused to try to get out, saying "Women first." All the other adult men but one fled, so it is stated, knocking down the unfortunate women, so as to get out the quicker, and making a shameful abuse of their strength. One adult man alone was seriously wounded—namely, Dr. Recamier, who saved many people, and who, having lost his hat, was severely burned on the back of the neck. Such professional devotion stands out in strong contrast with the abominable behaviour of certain of the men of fashion, who had no thought but to save themselves, and who actually increased the number of victims by their mad rushes and the blows which they struck. One of the dead is reported to have succumbed not to the effect of the burns but to a fracture of the skull produced by a heavy blow with a walking-stick.

The Treatment of Pott's Disease.

The forcible straightening of the spinal column in cases of curvature due to Pott's disease has become a common method of treatment with surgeons since the communication made by M. Calot. M. Menard, surgeon to the hospital at Berck, where M. Calot is also surgeon, has presented a report to the Academy of Medicine in which he lays stress upon the dangers and defects of the operation devised by his colleague. He has made some experiments upon the dead body and finds that in straightening the vertebral column in subjects affected with spinal curvature a separation of the bones occurs at the tuberculous spots, especially when the stretching is extreme, and that a communication is thus laid open with the meninges and the cord behind and the mediastinum and pleura in front. Further, it is well known

Hosted by Google

that the diseased foci in the bones are incapable of taking on a process of bony healing. M. Menard considers that curvatures treated by the method of M. Calot will tend to reproduce themselves. M. Menard has just read a second paper on the subject at the Society of Surgery, where M. Brun stated that his experiments on the dead body had been attended with similar results—a wide gap was produced between the vertebral bodies owing to their being pulled apart by the straightening. He had performed the operation on the living subject twice, and in these two cases the results after intervals of two and four months respectively were excellent, neither was there any relapse. MM. Michaux, Poirier, and Broca had all performed the operation many times, and found it easy and unattended with grave risks, but they agreed that more observations were needed before any definite conclusions as to its value could be arrived at.

The New Tariff for Night Visits.

A disagreement has recently arisen between the Prefect of Police and the surgeons attached to the Service Médical de Nuit of the Sixteenth Arrondissement with reference to the payment of fees for which the police are liable, the services having been rendered at the request of their officers. By a new regulation the prefecture bases its calculations upon the amount allotted for fees to each quarter, an average for three years being taken and every three months the whole sum should be divided among those to whom it may be owing. In the Passy quarter, however, the sanitary conditions for the three months, January, February, and March, were particularly favourable and accordingly the fee worked out at a sum of 23 fr. 50 c. for each visit The administration considered this too high, and one medical man sent in his resignation. With a view of healing the breach the prefecture proposed as a way out of the difficulty that visits made during the first three months of the year in the Passy quarter should be paid for at the rate of ten francs for every night call.

The Asylum for Lunatics.

To avoid the crowding of the infirmaries attached to lunatic asylums with cases of senile dementia—that is to say, with harmless lunatics who show no other signs of mental weakness than the mental feebleness common to the aged—the Prefect of the Seine has just invited the Assistance Publique to take measures to provide that only real lunatics shall be admitted into lunatic asylums. The Prefect of Police has accordingly addressed an important communication to all the police commissaries under him, in which he requests them to give no heed to applications made by hospital authorities for assistance in removing patients to a lunatic asylum, except when the hospital authorities can state that they have definitely decided that the patient is really mad. No one can be placed in an asylum by French law unless his mental state is such as to be a menace to public order or to other people. But the question of the disturbing of a hospital ward by a lunatic does not seem to have entered into the ken of this police notice. The Prefect requests his commissaries every time that they are applied to by a hospital for a removal order to demand the most explicit and accurate certificates from the medical men in charge of the patient. In cases where these certificates are not deemed sufficiently clear and full the commissaries are to decide for themselves as to the state of the patient from the point of view of public safety and to make every inquiry necessary for this purpose.

Appointments.

M. Chantemesse has been nominated Professor of Experimental Pathology at the Paris Faculty of Medicine in place of M. Strauss, deceased.—M. Rendu has been nominated a member of the Academy of Medicine.

May 18th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

A New Antitoxin for Tuberculosis.

PROFESSOR HIRSCHFELDER, of San Francisco, U.S.A., has published in the *Deutsche Medicinische Wochenschrift* a new method of treating tuberculosis. He considers that the cases in which tuberculous disease has been recovered from as shown by the healed lesions frequently found in post-mortem examinations may be explained on the supposition that the human organism is able to produce an antitoxin. The results hitherto obtained by artificial preparations of antitoxin have not been very satisfactory because sufficient attention has not been paid to the natural conditions. It is admitted that tuberculous peritonitis is sometimes cured by a simple laparotomy, and this fact supplies a valuable suggestion, for it is very probable that the entrance of air into the peritoneal cavity causes the bacilli of tuberculosis to disappear, in consequence of the tuberculin present in the abdomen becoming transformed by the atmospheric oxygen into oxy-tuberculin. Following up his theory that recovery from tuberculosis depends essentially on an oxidation process, Dr. Hirschfelder was led to the conclusion that by oxidation of tuberculin outside the body it might be possible to produce a powerful antitoxin in an unlimited quantity, and he has succeeded in satisfying himself that tuberculin treated with peroxide of hydrogen (H_2O_2) is deprived of its virulence, so that it may be administered in very large doses. The details of his process are as follows: 60 c.c. of tuberculin are mixed with 240 c.c. of a 10 per cent. solution of peroxide of hydrogen (H_2O_2) in a well-closed bottle, and the mixture is sterilised by exposure to the heat of steam for ninety-six hours. The fluid thus becomes opaque and has an acid reaction. It is now cleared by a solution of caustic soda, 5 per cent. of boric acid is then added, and after filtration the fluid is ready for use. The tuberculin used for this process is not that which was discovered by Professor Koch, but is prepared after Dr. Hirschfelder's own method. It is made of bacilli of high virulence, cultivated on a mixture of veal broth with 4 per cent. of glycerine, 1 per cent. of Witte's peptone, 0 5 per cent. of chloride of potassium, and 0 3 per cent. of carbonate of potassium. Advanced cases of pulmonary tuberculosis with extensive cavities are due to an infection by other bacteria as well as by the bacilli of tuberculosis. Under these circumstances oxy-tuberculin used alone is not capable of destroying the bacteria, and it is necessary to have recourse to another antitoxin made from the sputum of phthisical patients in a way similar to that in which oxy-tuberculin is prepared. Large quantities of this "oxy-sepsin" may be administered without any harm to the patient. As a rule, 20 grammes of oxy-tuberculin and 10 grammes of oxy-sepsin are to be injected. The lymph must be quite fresh, and if it has become opalescent it must be again sterilised for fifteen minutes. Ordinary antitoxin syringes were used for the injection of oxy-tuberculin. At first only oxy-tuberculin was employed, but eventually it was in advanced cases always combined with oxy-sepsin, and better results were thereby obtained. The administration does not cause any pain, and there is no inflammation at the place of the injection, the fluid being absorbed in a few minutes; no rise of temperature or other undesirable symptom was observed. In the course of a few days the cough and expectoration decreased, the appetite improved, and the patient felt better. Fever, as a rule, very soon disappeared, and physical examination of the lung showed a marked amelioration of the tuberculous infiltration. The first patients were treated in November, 1895, and the good effect produced has been maintained ever since. The most suitable cases for treatment are those in which cavities have not yet formed, and especially those of laryngeal tuberculosis, where the improvement may be directly observed with the laryngoscope. A tuberculous ulcer on the back of a medical man's hand healed in a short time under the local application of oxy-tuberculin, after all other remedies had proved useless. Dr. Hirschfelder gives a detailed account of eight cases of pulmonary tuberculosis where the bacilli disappeared and the patient's general health improved in the course of the treatment. He states that he has also cured cases in a more advanced stage, and promises to publish his results at some future time, the object of the present communication being only to demonstrate that the antitoxin is practically an oxidised toxin. According to him, pneumonia, empyema, and streptococcus infection are also capable of being treated by their respective oxy-toxins, and the same is probably the case in all infectious diseases. He has also made experiments with carcinoma, but the number of cases is too small to, as yet, justify a definite expression of opinion.

The Radical Cure of Hernia.

Professor Kocher, of Berne, Switzerland, has recently published in the *Centralblatt für Chirurgie* the results of the

Hosted by Google

operations performed by him for the radical cure of hernia. He operates by a method in which the sac, after being isolated from its surroundings, is drawn through an incision in the internal oblique muscle, and without being opened is fastened there by a series of sutures. In contradiction of a statement made by Dr. Coley, of New York, he points out that his results were at least as satisfactory as those obtained by Bassini's method. From 1894 to 1896 he performed 197 operations, of which 103 were inguinal herniæ. In 91·3 per cent. healing by primary intention took place, so that the patient could be discharged in from ten to eleven days. In 8·7 per cent. the wound healed more slowly, owing to the presence of secretion. The average duration of a case was between thirty-two and thirty-three days. In eighty-eight cases of the present series and in twenty-three of a former series the condition of the patients was examined a considerable time after the operation. Of these 111 cases of inguinal hernia, four cases (= 3·6 per cent.) suffered from relapses. Of the cases that were positively cured, twenty-six were operated on in 1896, thirty-five in 1895, twenty-four in 1894, and twenty-three in 1893. The mortality of the operation was, in fact, *nil*. Compared with the figures given by Dr. Coley for Bassini's method, the results seem to be a little less favourable. But of the 360 patients mentioned by Dr. Coley, no fewer than 250 were children, in whom the results of operation are invariably better than in adults. Professor Kocher finally suggests a modification of the above-described method of operating.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Step in the Right Direction.

THE conflict between medicine and law when, in criminal trials, the line has to be drawn between organic lesion (hereditary or acquired) and moral responsibility is of longer standing and of more embittered tenour in Italy than in any other State. To bring about, if not an *entente cordiale*, at least a *modus vivendi*, between the two interests, scientific and legal, has for some time been under serious consideration by leading minds in both professions, and, as a first step towards the desired consummation, the University of Siena has begun a series of inter-professional conferences between the students of the two faculties, culminating in visits to the penitentiaries, or criminal asylums, where the relations between organisation and crime can best be studied in the concrete. On Saturday, the 8th inst., Dr. Salvatore Ottolenghi, Professor of Legal Medicine in the Siena school, and Dr. Ugo Rossi, an expert in psychiatry, conducted forty students drawn in about equal numbers from the medical and juristic classes on a visit to Volterra, there to profit by the object-lessons in its famous penitentiary. The conversazione held that evening in the civic "Accademia," at which ideas on the subject of common interest were pleasantly exchanged, was followed next day by a prolonged inspection of the penitentiary itself—its laboratories, and its special wards and cells. Professor Ottolenghi, with the aid of the director of the institution, Signor Querci, and its resident physician, Dr. Verdiani, selected three typical specimens of the kind and degree in which physical or physiological deterioration may affect moral activity. The demonstrations were carried through three stages: (1) the "esame somatico" (examination of the bodily condition as a whole, (2) the "esame antropometrico" (the response to anthropometric tests), and (3) the "esame psichico" (the psychological examination). The findings under each of these heads were compared with the history, intellectual and moral, of the subject, and the conclusions, diagnostic and clinical, drawn with equal care, the whole exposition being effected with that method and lucidity of diction characteristic of the Sienese professor. At the banquet which followed Dr. Ottolenghi dwelt on the objects of the inter-professional excursion, auguring its successful imitation by other schools and anticipating the best results in practice from the experience conjointly shared by the future physician and the future barrister.

May 17th.

Obituary.

ADOLPHUS JOSEPH RICHARDSON, M.A., M.D. CANTAB., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE SUSSEX COUNTY HOSPITAL.

BY the sudden death of Dr. Adolphus Joseph Richardson, at the age of forty-one years, the staff of the Sussex County Hospital and the medical profession in Brighton have lost one of their most able colleagues. Dr. Richardson, familiarly known by his friends and at the London Hospital as "Doctor Dolly," received his early education at the City of London School, where he gained the Mortimer Medal, and on leaving this school in 1875 he obtained an entrance exhibition, and afterwards a natural science scholarship at King's College, Cambridge. He graduated B.A. in the mathematical and also in the Natural Science Tripos in 1878; subsequently he took the degree of M.A. At the London Hospital he gained the Entrance Natural Science Scholarship, and subsequently the Letheby Chemical Scholarship. He held the resident appointments of house physician (under the late Sir Andrew Clark), house surgeon, and resident accoucheur. He also studied medicine in the University of Vienna. He was admitted a Licentiate of the Society of Apothecaries in 1881, a Member of the Royal College of Surgeons of England in 1882, and took the M.B. at Cambridge and became a Member of the Royal College of Physicians of London in 1883. He obtained the D.P.H. Eng. in 1888, and in 1889 proceeded to the M.D. degree at Cambridge. On a vacancy for assistant obstetric physician occurring at the London Hospital Dr. Richardson, though cordially supported by the professional staff of the hospital, failed to obtain the appointment. Hereupon he left the London Hospital and settled in practice at Hove, Brighton. In November, 1887, he was elected an assistant physician of the Sussex County Hospital. To the welfare of this institution he devoted much time, and he took a prominent part in the hospital extension scheme. He was appointed an Examiner in Medicine to the Society of Apothecaries of London, being at that time the only member of the board of examiners who was unconnected with one of the leading London hospitals, and it is within the knowledge of the writer that Dr. Richardson might have become a Fellow of the Royal College of Physicians of London but for the circumstance that he was not yet prepared to relinquish altogether general practice in favour of consulting work.

It is to be regretted that Dr. Richardson's early death has put an end to certain researches which he pursued through a course of several years—notably, the causation and the treatment of the anæmia and chlorosis so prevalent in and around Brighton. In this connexion he contributed a letter to THE LANCET on "Bruit de Diable in Chlorosis" in June, 1891, criticising a paper read before the Royal Academy of Medicine in Ireland, an abstract of which was published in THE LANCET the previous May, and dissenting from the conclusions arrived at by the writer. He also contributed articles to THE LANCET on Infantile Spastic Paralysis in 1888, on Antipyrin in 1889, and on a case of Tuberculosis with Jaundice and Ascites in 1894. He was a prominent member of the South-eastern Branch of the British Medical Association, at the meetings of which he read several important papers. His study of mathematics and natural science did not cease when he had taken his degree, and his constant endeavour was to keep himself thoroughly acquainted with the progress of science, with a view to bringing the knowledge thus acquired to bear on the practice of his profession—a profession he had chosen for himself and which he loved with an unselfish love.

At the time of his death he was president of the Hove Camera Club. With the application of the Roentgen rays to photography a new era opened for him; he at once adopted the principle and applied his photographic knowledge to the diagnosis and treatment of disease. But among those who knew him best Dr. Richardson will not be remembered solely for his intellectual attainments. He was a man of commanding physical presence, and believed in the necessity of training the body as well as the mind, he himself being no mean proficient in many sports. At Cambridge he was captain and stroke of his College boat and was one of the crew of the London Hospital Rowing Club in the first inter-hospital boat race. At one time he was well known in the

Hosted by Google

hunting field with the South Down Fox-hounds, but through pressure of professional work he was obliged to relinquish this form of sport. Realising, however, that he needed some form of exercise he spent the few hours of leisure at his command in bicycling, generally accompanied by his wife, and carrying a camera. His photographic pictures of some of the most charming spots in the county of Sussex are among the results of these expeditions.

Dr. Richardson had only returned a few days from a holiday spent in Egypt when he considered it his duty to visit gratuitously a patient at Buxted, and he rode thither on his bicycle on Friday, April 23rd. He had travelled down Buxted Hill with his feet on the foot-rests and had proceeded some distance along the level road, when on attempting to take his pedals he was thrown violently to the ground. He sustained concussion of the brain, cuts over the bridge of the nose, and some laceration of the lips. A gentleman passing the spot in his carriage drove him to the house of Mr. Birt, of Uckfield, where he was hospitably received and professionally attended to. On the Saturday he was removed to a private house in the village, and on the next day he stated his belief that he would be attacked by tetanus, and that he should die on the following Sunday or Monday. Dr. Black, assistant surgeon of the Sussex County Hospital, who had come to Uckfield to attend his colleague in conjunction with Mr. Thomas (Mr. Birt's representative), endeavoured to dispossess him of this idea, but nevertheless procured the serum necessary for the antitoxic treatment of tetanus. On Thursday (the 29th) Dr. Richardson stated that he experienced some stiffness in moving his jaw, and though his medical attendants could discover no symptoms of tetanus Dr. Black yielded to the entreaty of his colleague and commenced the serum injection. From that time until Dr. Richardson's death Dr. Black practically never left his friend's side. Symptoms of tetanus were well marked on the Friday, and Dr. Richardson succumbed to the disease on Sunday, May 2nd. Dr. Richardson leaves a widow and one daughter.

The first part of the funeral service took place in Hove Parish Church, and the large attendance of mourners spoke eloquently for the esteem and respect in which Dr. Richardson was held by those amongst whom he had lived and worked. Practically the whole of the medical profession of Brighton, including the staff of the Sussex County Hospital, the chairman, the vice-chairman, and the committee, the matron, and many of the nursing staff of the hospital, and numerous friends and patients, were present. The interment took place at Portsmouth; Dr. Hollis and Dr. Black, as representing the Sussex County Hospital, attended at the grave side, where also were collected numerous friends who had travelled from London and elsewhere. The service at the Parish Church, Hove, was conducted by the Vicar of Hove (the Rev. Prebendary Peacey) and the Rev. A. D. M. Gowie (Curate of St. Patrick's, Hove), a personal friend of the deceased; that at Portsmouth by the Rev. E. Lunt, of Bath, and the Rev. A. D. M. Gowie.

JOHN ROBERTSON, M.B., C.M., B.Sc. EDIN.

ON April 6th Dr. John Robertson died quite suddenly at his residence, 30, Lauriston-place, Edinburgh, aged forty-seven years. The deceased was a native of Forfarshire and studied at the Universities of St. Andrews and Edinburgh, graduating at the latter as Bachelor of Medicine, Master of Surgery, and Bachelor of Science in 1876. His career as a student was exceptionally brilliant so much so, that he was known to his fellows as "the great medalist." After he qualified he practised for a short time at Langholme in Dumfriesshire, but soon removed to Edinburgh, where he was appointed district medical officer of the city of Edinburgh parish. For some time also he held the post of Lecturer on Diseases of the Eye at the Minto House School of Medicine, but relinquished the appointment as his time began to be more occupied by the increasing demands of a growing practice. He was popular and a hard worker, and his comparatively early death will be a source of sorrow to his many friends.

THOMAS FRANCIS FERNANDEZ, M.D. GLASG., F.R.C.S. ENG.

DR. FERNANDEZ died at his residence, Brookfield, Ross, Herefordshire, on May 4th, after a short illness. The deceased was born in London in 1815 and graduated M.D. Glasg. in 1837, taking the M.R.C.S. Eng. in the following year. He was admitted F.R.C.S. Eng. in 1852. Dr. Fernandez entered the Indian Medical Department in 1838, and after having seen twenty-five years' service retired in 1863. In 1867 he settled in practice at Ross. He held, among other appointments, that of medical officer of health for the district for several years and was highly respected in the neighbourhood.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination for the diploma of Fellow at a meeting of the Board of Examiners on Monday, the 10th inst.:—

Alex. Wathen Nuthall, M.R.C.S. Eng., L.R.C.P. Lond., Mason College, Birmingham, and St. Bartholomew's Hospital; Joseph Moreton, B.Sc., Vict. Univ., Owens College, Manchester; William Billington and Harry Ellis Brawn, Mason College, Birmingham; and Hubert Middlecott Fletcher, University College, Liverpool.

Fifteen gentlemen were referred back to their professional studies for six months.

Tuesday, 11th inst.:

Whitley Bland Stokes, M.R.C.P. Lond., M.D. T.C.D., Trinity College, Dublin, and St. George's Hospital; Herbert John Paterson, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.C. Cantab.; Llewellyn Caractacus Powell Phillips, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.C. Cantab., Cambridge University and St. Bartholomew's Hospital; George Constable Hayes, M.R.C.S. Eng., L.R.C.P. Lond., Melbourne University and King's College Hospital; Dudley D'Auvergne Wright, M.R.C.S. Eng., L.R.C.P. Lond., University College Hospital; Ernest Harding Freeland, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., Middlesex Hospital; Frank Barnes and John Bradley, Mason College, Birmingham; and William George Porter, Charing-cross Hospital.

Seven gentlemen were referred back to their professional studies for six months.

Wednesday, 12th inst.:

Graham Scales Simpson, L.D.S. Eng., Guy's Hospital; Frederick Fen Elwes, Middlesex Hospital; and Ernest Lewis Lilley, Charing-cross Hospital.

Thirteen gentlemen were referred back to their professional studies for six months.

Thursday, 13th inst.:

Ambrose John Rodocanachi, M.D., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., University College Hospital; Archibald Robert John Douglas, M.R.C.S. Eng., L.R.C.P. Lond., M.B., B.S Lond., and Frederick Charles Borrow, St. Bartholomew's Hospital; Herbert James Phillips, St. Thomas's Hospital; and Caleb Thomas Hilton, Guy's Hospital.

Eleven gentlemen were referred back to their professional studies for six months.

Friday, 14th inst.:

John James Evans, M.B. Edin., M.R.C.S. Eng., L.R.C.P. Lond., Edinburgh University and Mason College, Birmingham; Thomas Alfred Mayo, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; and Walter Bernard Secretan, Guy's Hospital.

Thirteen gentlemen were referred back to their professional studies for six months.

Monday, 17th inst.:

John Ford Northcott, B.A. Cantab., Cambridge University and Guy's Hospital; Peter Lewis Daniel, Charing-cross Hospital; and Sydney Richard Scott, St. Bartholomew's Hospital.

Thirteen gentlemen were referred back to their professional studies for six months.

Tuesday, 18th inst.:

James Morrison, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital; Brennan Dyball, M.R.C.S. Eng., L.R.C.P. Lond., Walter Andrew Bowring, M.R.C.S. Eng., L.R.C.P. Lond., and John Leay Prain, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital; and Douglas Phillimore Gabell, M.R.C.S. Eng., L.R.C.P. Lond., L.D.S. Eng., Charing-cross Hospital.

Eight gentlemen were referred back to their professional studies for six months. Of the total number of candidates at this examination—viz., 113—thirty-three passed and eighty were referred—i.e., nearly 71 per cent.

The following are the arrangements for the Final Examinations for the diploma of Fellow, for which forty-six gentlemen have entered their names:—

Monday, 24th inst.—Written Examination at the Examination Hall, 1.30 to 5.30 P.M.

Tuesday, 25th inst.—Clinical Examination, written and *vivâ-voce*, at the Examination Hall, 2.30 to about 6.30 P.M.

Wednesday, 26th inst.—Operations at the Examination Hall, 1.30 to about 6 P.M.

Thursday, 27th inst.—Surgical Anatomy at the Examination Hall, 2 to 4.15 P.M.

Friday, 28th inst.—Pathology, *vivâ-voce*, at the Royal College of Surgeons, 5 to about 7.30 P.M.

Saturday, 29th inst.—Pathology, *vivâ-voce*, at the Royal College of Surgeons, 5 to about 7 P.M.

All candidates will be required to attend on the first four days and on Friday or Saturday.

ENLARGEMENT OF THE BRISTOL LUNATIC ASYLUM AT FISHPONDS.—At the quarterly meeting of the Bristol town council, held on May 11th, it was decided to erect four new wards at the Bristol Lunatic Asylum, Fishponds, to accommodate 150 additional female patients, also a nurses' annexe, a dining and recreation hall, and an isolation hospital. With these additions the asylum will afford accommodation for 391 males and 550 females. It is estimated that the improvements will cost £31,000. With these alterations Bristol will still have an economically constructed asylum, as the cost will be less than £210 per bed.

BRITISH HOME FOR INCURABLES.—The annual meeting of the British Home for Incurables was held at the City Terminus Hotel on May 18th, Earl Amherst presiding. The report showed that the work of the institution was being carried on satisfactorily, the subscriptions, donations, patients admitted, and annuitants in receipt of pensions all exceeding those of the preceding year. The annual subscriptions amounted to £3072, donations to £3988, and legacies to nearly £5000; the number of pensioners receiving £20 a year each was 300. There were sixty-five patients in the home at Streatham, and the home at Margate was well filled during the summer.

THE PLAGUE IN BOMBAY.—The Secretary of State for India has received the following telegram from the Governor of Bombay on the subject of the plague:—"Deaths from all causes in Bombay city for week ended May 14th, 543; reported plague deaths, 81. Poona city, for week ended May 14th, deaths from all causes, 31; reported plague deaths, 13; fresh attacks, 13. Total of Haffkine's inoculations: Bombay, 7775; elsewhere, 4184. Local cases for week ended May 14th: Surat district, 26 cases, 21 deaths; Thana district, 61 cases, 54 deaths; Kolaba district, 113 cases, 94 deaths; Kathiawar, 11 cases, 10 deaths; Cutch, 840 cases, 811 deaths; Kolhapur, 2 cases, 3 deaths; Baroda, 23 cases, 18 deaths; Palanpur, 2 cases, 3 deaths; no cases Ratnagiri, Poona, and Ahmedabad districts or Ahmedabad city during week. Two attacks, one death, amongst English people. Arrangements being made for plague hospitals and observation places suitable for the rainy season. During week plague deaths: Karachi, 44; Haldarabad, 11; Sukkur, 5; Rohri, 18."

LITERARY INTELLIGENCE.—The Rebman Publishing Company announce as in press and to be issued forthwith a new work on heart disease, entitled "Cardiac Failure and its Treatment, with especial reference to the use of Baths and Exercises," by Dr. Alexander Morison, physician to the Great Northern Central Hospital, London. The book will include an appendix by Medicinalrat Dr. Groedel of Bad Nauheim.—Messrs. Baillière, Tindall, and Cox, announce that Sir William Broadbent's new work on "The Heart" will be ready in a few days, and that they will also publish during the present month a new "Clinical Manual of Mental Diseases," by Dr. Clark, superintendent of the Lanark County Asylum; a work on "Disease of the Gall-bladder and Bile Ducts," by Mr. Mayo Robson, Hunterian professor at the Royal College of Surgeons; a translation of Professor Landau's work, "The History and Technique of Vaginal Operations," by Dr. Giles and Dr. Eastman; and a third edition of Dr. Ball's manual, "Diseases of the Nose and Pharynx."

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of this society was held on the 18th inst. The following resolution was moved by Mr. Joseph Smith, seconded by Dr. Alderson, and carried unanimously: "That the committee of this society has heard with the deepest regret of the death of Mr. Walter Rivington, F.R.C.S., and begs to tender to the family its sincere sympathy and condolence. The committee feel that by the death of Mr. Rivington the Members of the College have lost one of their staunchest friends and one who for years was willing to assist them in every way, even to the sacrifice of his own personal interests." In moving the above resolution Mr. Smith said that Mr. Rivington's singular modesty of character and entire self-abnegation endeared him to all with whom he came into contact. Knowing how near to the heart of Mr. Rivington the reform of the College was, the Members ought to work with renewed vigour in the cause he loved so well, and not to cease from their labours until their object was attained. Let us all remember Mr. Rivington's motto, "Every man is a debtor to his profession."

CHURCH SANITARY ASSOCIATION.—At the fifth annual meeting of the Church Sanitary Association, held last week at 1, Hamilton-terrace, London, a motion recommending the substitution of the Scottish method of swearing with uplifted hand in place of the present system of kissing the Book, was proposed by Dr. Walsh, seconded by the Rev. J. V. Mason, and carried.

UNIVERSITY OF CAMBRIDGE.—The feeling against the proposal to admit women to titular degrees is growing in intensity, and is so strong among the resident teachers that Dr. Ryle, President of Queen's, Mr. J. W. Clark, Registrar, and the senior tutors of Caius and Clare Colleges, have felt constrained to withdraw their support and to urge the rejection of the Graces. Others on the Women's Committee are understood to be contemplating a like step. It is felt that the redress of a nominal grievance might be too dearly purchased if a majority of those who carry on the work of the University were forced by the non-resident voters into a position of embittered hostility to the cause of women's education. It is they who would be concerned with the practical realisation of any plan which might be imposed on the University by the vote of the Senate at large, and the present facilities for the real education of women, which rest solely on a basis of personal acquiescence on the part of the professors and other heads of departments, are in danger of serious curtailment if, as many think, the titular recognition accorded to women students should result in a serious diminution in the number of male undergraduates, who have the first claim on the resources of the University. The result of the voting will be made known about 4 P.M. on Friday afternoon.—Mr. W. N. Shaw, F.R.S., has been appointed University Lecturer in Experimental Physics.—At the congregation on May 13th Mr. T. A. Bowes, B.A., B.C., of Caius, was admitted to the degree of M.D.; Mr. C. F. Lillie, B.A., B.C., of St. John's, to the degree of M.B.; and Mr. F. H. Blatchford, B.A., of Sidney Sussex, to the degrees of M.B. and B.C.

DIPHTHERIA IN LONDON.—In the four weeks ended on March 27th last there had been notified in London 902 cases of diphtheria, yielding a weekly average of 226 cases, every sanitary area having been invaded. Not only so, but in five areas 335 cases had been notified, and the per case mortality rate for diphtheria in London, as judged by the registered deaths in the period, was 19 5 per cent. of notifications. The deaths had numbered 176, or 44 weekly. But these data were generally very favourable when placed beside those for earlier periods of the present year and of the closing months of 1896. In the four weeks ended on April 24th the improvement has been more than maintained. There were only 730 notified cases in London, although all save one of the sanitary districts were invaded. But only two of the districts had upwards of 50 cases each—these two having an aggregate of 127 notifications—whilst seven of the districts contributed upwards of one-third of the total notifications. In other nine districts only 25 notified cases were recorded in all. The average weekly number of notifications in London fell to 182. The registered deaths numbered 134, or 33 weekly, and the per case mortality, reckoned on these deaths, was 18 4 per cent. of notifications.—In the three several weeks completed on May 1st, 8th, and 15th the registered deaths from diphtheria in London have been 40, 26, and 42 respectively. The 26 deaths in the middle of the three weeks were 6 below the corrected decennial average for the eighteenth registration week of the period 1887-96, and all of them were of young persons aged under twenty years, only 1 being an infant and 8 over five years of age. In Paddington, Islington, and Lambeth severally 4 deaths occurred. But if the deaths in London from diphtheria were few, so also were those in the outer ring, only 2 being recorded in the suburban districts—namely, 1 in Chiswick and 1 in East Ham. Last week the registered deaths from the disease in London rose to 42, a number which was 9 in excess of the corrected decennial average for the particular week, 2 being of infants and 10 of young persons aged from five to twenty years, only 3 being of persons over the latter age. In both Islington and Bethnal-green sanitary areas 4 deaths occurred. Last Saturday left 761 diphtheria patients under treatment in hospital, the fresh admissions during the week having been 94 in number. In the outer ring there were 7 deaths in the week, single deaths belonging to Mitcham, Hillingdon, Acton, Willesdon, Stratford, and Plaistow sub-districts.

PRESENTATIONS TO MEDICAL MEN.—Mr. William H. Davis, L.S.A., of Low Fell, Gateshead-on-Tyne, has received as an acknowledgment of his services the gift of a silver cake dish from the members of the Low Fell ambulance classes.—His Worship the Mayor of Southport (Dr. G. H. Pollard), distributed, in the Mayor's parlour, on the 5th inst. the certificates to successful members of the class held under the auspices of the Southport Centre of the St. John Ambulance Association, and after the distribution presented, on behalf of the locomotive department of the Lancashire and Yorkshire Railway Company at Southport, to Mr. Stanley Melville, L.R.C.P. Lond., M.R.C.S. Eng., a dressing case, in recognition of his gratuitous instruction.—On May 5th Mr. F. Charles Berry, B.A., M.D., B.Ch. Dub., of Burnham, Somerset, the honorary lecturer to the Technical Committee, was presented by the Rev. Gerald Pippin, on behalf of the members of the St. John Ambulance Class, with a handsome copy of Crookshank's "Bacteriology." Subsequently a corps of the St. John Ambulance Association was formed with Dr. Berry as president.—Mr. Walter Dickson, M.B. Edin., of Hungerford, has received a present of a case of pipes from the Hungerford Ambulance class, as a thank-offering for his honorary instructions on ambulance aid.—Mr. Meredith Young, M.B. Edin., D.P.H. Vict., on his leaving Brighouse, has been presented by the Hipperholme and Lightcliffe Ambulance Classes, in connexion with the St. John Ambulance Association, in recognition of his valuable services as their instructor, with a large Gladstone bag, bearing the following inscription: "Presented to Dr. Young by the Hipperholme and Lightcliffe Ambulance Classes, April 29th, 1897."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Infant Life Protection Bill.

IN its passage through Committee in the House of Lords the Infant Life Protection Bill was considerably strengthened. It now provides not only that the person who keeps more than one child for hire or reward shall give notice of the fact to the local authority, but that the local authority shall from time to time make inquiry as to the state of things in this connexion within its jurisdiction. Further, it is laid down that the local authority shall see to the enforcement of the Act "by appointing inspectors, or arranging for the infants being visited by ladies nominated by the local authority and authorised by it in writing to enforce the provisions of this Act." Another change made was to substitute the board of guardians for the borough or district council as the local authority under the Act.

Venereal Disease amongst the Troops in India.

This subject was debated in the House of Lords on Friday, May 14th, and on Monday, May 17th. The debate was introduced by the Earl of Dunraven, who moved for the institution of an inquiry into the effect of venereal diseases "upon the forces of the Crown, the civil population and the native races within her Majesty's dominions and into the nature and results of the measures which are, or have been, in force in this and other countries for the prevention of such diseases." Among those who took part in the debate were the Archbishop of Canterbury, Lord Roberts of Kandahar, Lord Lister, who on this occasion delivered his "maiden speech," Lord Playfair, the Marquis of Lansdowne, and the Earl of Kimberley. The position taken by the Government was that the time is past for such an inquiry, that immediate action is imperative, and that the Government of India has the matter in hand, and is doing its best to grapple with it. In view of this, Lord Dunraven withdrew his motion at the close of the debate.

HOUSE OF COMMONS.

THURSDAY, MAY 13TH.

Midwives Registration Bill.

Mr. Lough, on behalf of Mr. Hazell, asked the First Lord of the Treasury whether his attention had been called to the Midwives Registration Bill now waiting its second reading in this House; whether he was aware that the Bill carried out the unanimous recommendations of the Select Committee of the House of Commons on the subject, and that Bills with this object had been introduced time after time into Parliament, but that they had been dropped through failure to secure Parliamentary time; and whether, in view of the large amount of mortality and widespread suffering both of mothers and of infants which the Committee reported, the Government would give time during the present session for the discussion of the Bill now before the House, and, if this were not possible, whether they could hold out hope of its being made a Government measure next session.—Mr. Balfour replied: The hon. gentleman asks me to give special facilities for the discussion of a private Member's Bill. Without expressing an opinion upon the merits of the Bill I think the House will see that it is a course to which the Government cannot consent.

The Salt Tax in India.

Sir William Wedderburn asked the Secretary of State for India, whether he was aware that there was a very general feeling in India that the high duty on salt should be reduced for this year at least, in view of the sufferings of the poorer classes from famine, the loss of revenue caused thereby being included in the cost of famine relief; whether he was aware that such reduction could be effected by an executive order of the Government of India; and whether he would direct the Government of India to issue such an order.—Lord George Hamilton, in reply, said he was not aware that there was any general feeling in India that the salt duty should be reduced for one year. He might, on the contrary, point out that any such limitations of the period of reduction would be practically impossible, because, if an abatement for one year only were announced, enough salt for consumption during a very much longer period would undoubtedly be drawn out of bond or otherwise passed into stock within the year. The price of salt was now for the majority of people in India lower than it was twenty, thirty, or forty years ago, and the incidence of the duty was about 4½*d.* per head per annum. In these circumstances, although he felt most deeply for the sufferings which a large number of Her Majesty's Indian subjects had been and were undergoing, he did not purpose to issue any orders with regard to the salt duty.

The Notification of Infectious Diseases.

Sir John Brunner asked the President of the Local Government Board how many local authorities had adopted the Notification of Infectious Diseases Act, and what proportion that number was of the whole number empowered to adopt it.—Mr. Chaplin replied: Excluding London, where the notification of infectious disease is compulsory under the Public Health (London) Act, 1891, the Local Government Board have up to May 11th, 1897, received information of the adoption of the Infectious Diseases (Notification) Act, 1889, in 654 rural districts out of a total of 671 rural districts, and in 904 urban districts out of 1088 urban districts. But in 49 of the 184 urban districts where the Act of 1889 has not been adopted the notification of infectious disease is compulsory under provisions in local Acts.

The Adulteration of Food and Drugs.

In reply to a question on the subject of the introduction of the promised Bill to amend the Sale of Food and Drugs Act, Mr. Balfour said he had been in consultation with the President of the Local Government Board, but he was not yet able to fix a day.

East London Water-supply.

Mr. Gray moved an instruction to the Committee on the East London Water Bill, giving them power to insert a clause providing that the term "the annual rateable value of the tenement supplied with water" shall have the same meaning in the districts outside the metropolis supplied by the Company as the term now has within the metropolitan area. Mr. Gray argued that people getting the same supply and living in the same neighbourhood should be charged the same rates for the water. Objection was taken to the motion on the ground that if carried, and this provision were inserted in the Bill, it would put the East London Company in a different and less favourable position than other water companies. Mr. Chaplin, in particular, argued that such a matter as this, if dealt with at all, should be dealt with in relation to all water companies. As the outcome of the debate, the motion was withdrawn.

Poor-law Officers Superannuation Act.

The Bill to amend the Poor Law Officers Superannuation Act of last year was, without debate, read a second time at this sitting.

FRIDAY, MAY 14TH.

Reformatories for Inebriates.

Mr. Balfour, replying to Dr. Farquharson, said he did not think that there was any probability of the Bill for the establishment of reformatories for inebriates being introduced during the present session.

The British Troops in India.

Mr. Stuart-Wortley asked the Secretary of State for India whether he had received any representative memorials or petitions from the general public on the subject of the proposals contained in his despatch of March 26th, 1897, for improving the health of the British troops in India, and if so whether he had any objection to make them public.—Lord George Hamilton said he had received only two memorials which could be held to be representative of general public opinion on the subject of his despatch regarding the health of the British troops in India, and he had no objection to making them public. A few memorials had also been received from local meetings and societies embodying protests against the action taken by Her Majesty's Government.

MONDAY, MAY 17TH.

Medical Establishment of the Foot Guards.

Dr. Farquharson asked the Under Secretary of State for War whether he was aware that the medical department of the Brigade of Foot Guards was short-handed, and that much difficulty was experienced in filling vacancies in consequence of insecurity of tenure and the expense of living in London; whether an official application was lately made by the commanding officers of the three regiments of Foot Guards for a return to the regimental system; and whether the War Office was prepared to give sympathetic consideration to this request.—Mr. Brodrick replied that there was at present one vacancy on the medical establishment of the Foot Guards. Appointments were made from medical officers who volunteered for the service, and as the appointments were for a fixed term of five years there was no insecurity of tenure. The officers commanding the regiments did recently suggest a return to the old regimental system, but under the existing system no difficulty had hitherto been experienced in finding candidates for the appointments.

University of London Bill.

Mr. Balfour, answering a question addressed to him by Mr. Brynmor Jones, said that the President of the Council hoped to introduce this Bill shortly in the House of Lords. There was some reason to expect that the difficulties which prevented it from passing last year would be removed and certain negotiations were going on with that object.

Hosted by Google

TUESDAY, MAY 18TH.

Suggested Royal Corps of Army Surgeons.

Dr. Farquharson asked the Under Secretary of State for War, in view of the fact that in 1879 the War Office agreed to the issue of a warrant sanctioning the formation of a Royal Corps of Army Surgeons, whether he could state the reasons why legislative effect was not given to this recommendation: and, whether the present War Office was prepared to follow the example of its predecessor.—Mr. Brodrick said that a proposal to constitute the medical officers a corps of Royal Army Surgeons was made and considered in 1879, but was not adopted. He had explained already the reasons which make the Secretary of State unwilling to re-open the question.

Lock Hospital Patients.

Mr. Jeffreys asked the Under Secretary of State for War, whether he had received a copy of the unanimous resolution lately passed by the Committee of the Aldershot Lock Hospital to the effect that the attention of the Government should be called to the advisability of insisting on the patients in home lock hospitals being detained until free from infection, as in other dangerous infectious or contagious diseases; and whether he could take steps to carry out this resolution.—Mr. Brodrick replied that there was not now at Aldershot a lock hospital under military control, but the Government subscribed to a certain number of beds in the Hartley-Wintney and Farnham Union. A resolution from the committee of the hospital of the union had been received by the Secretary of State. While sympathising with the object of the resolution, the Secretary of State had no power to make regulations for the treatment of patients in union hospitals.

Water-supply in Rural Districts.

At this sitting Colonel Jo)rell introduced a Bill for giving facilities for a pure water-supply in rural districts.

WEDNESDAY, MAY 19TH.

Poor-law Officers Superannuation.

At this sitting an attempt was made to pass through the Committee stage the Poor-law Officers Superannuation Act (1896) Amendment Bill. When several members moved to report progress, Mr. T. W. Russell, Parliamentary Secretary to the Local Government Board, explained that last session the Government entered into an arrangement that nurses should not be included in the scheme of superannuation, but a mistake was made and they were included, and the whole object of the Bill was to remedy this mistake. The Bill, therefore, did not extend, but limited, superannuation, and in these circumstances he hoped the stage would not be opposed. This appeal was not, however, successful, and the stage had to be postponed.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ARMSTRONG, JOHN RICHARDSON, M.D. Edin., M.B, C.M., has been appointed Surgeon to the Cwm Park and Cwm Dare Pits, Ocean Collieries, Treorchy R.S.O., Glamorganshire, vice James Rowland James, deceased.

ARNISON, W. C., M.D. Durh., M.R.C.S., has been appointed an Honorary Consulting Surgeon to the Newcastle Royal Infirmary.

BLACKER, E., M.D. Durh., L.R.C.P. Edin., M.R.C.S., has been appointed a Physician to the Southampton Dispensary.

BRIGGS, R. W., M.B., C.M. Edin., L.R.C.P., M.R.C.S., has been appointed Resident Surgical Officer to the Birmingham and Midland Free Hospital for Sick Children.

BRUNYATE, T. T., M.D. Oxon, has been appointed Clinical Assistant to Out-patients at the Chelsea Hospital for Women.

BURTON, R. G., M.D. Edin., L.R.C.S., has been appointed Medical Officer of Health by the Greenford Urban District Council.

BYFORD, WILLIAM F., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Chesterfield and North Derbyshire Hospital.

COX, R. F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Knighton Rural District Council.

CRONE, JOHN S., L.K.Q.C.P. Irel., and L.S.A., has been appointed Public Vaccinator for No. 1 District of the Parish of Willesden.

DALE, ARTHUR J., M.B., B.S. Durh., has been appointed an Honorary Medical Officer to the Stockton Hospital, vice H. Hind.

DAWSON, C. R., has been appointed a Dentist to the Southampton Dispensary, vice T. P. Payne.

DILLON, L. C., L.S.A., has been appointed an Assistant Medical Officer to the Bracebridge Asylum, Lincolnshire.

DURRANT, CHARLES E., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Assistant House Surgeon to the Taunton and Somerset Hospital, Taunton.

DYKE, THOMAS JONES, F.R.C.S. Eng., L.S.A., has been re appointed Medical Officer by the Gelligaer Rural District Council, South Wales.

FERNANDES, R. W. L., M.B., C.M. Edin., has been appointed Medical Officer for the Second Sanitary District of the Hemsworth Union.

FORBES, T. D., M.B., M.S. Edin, has been appointed First Assistant Medical Officer for the Workhouse Parish of Bethnal-green.

GENGE, G. G., M.B., B.S. Lond., D.P.H. Camb., M.R.C.S., L.R.C.P., has been appointed Resident Medical Officer for the Croydon Borough Hospital.

GOULD, J. E., M.D. Lond., L.R.C.P., M.R.C.S., D.P.H. Camb., has been appointed Medical Officer of Health by the Sheffield City Council.

GREEN, T. CAROLINE, M.D. Brux., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer to the Lincoln County Asylum.

GRIMSDALE, T. B., M.D. Cantab., M.R.C.S., has been appointed an Honorary Medical Officer to the Liverpool Hospital for Women, vice J. B. Edis.

HIND, HENRY, F.R.C.S., M.R.C.S., has been appointed an Honorary Consulting Physician and Surgeon to the Stockton and Thornaby Hospital.

JEKYLL, L. N., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Leytonstone and Wanstead Sanitary District, vice C. R. Walker.

JONES, G. D. E., F.R.C.S. Eng., L.R.C.P., has been appointed Assistant Medical Officer for the Workhouse of the Township of Toxteth-park.

KELLY, BRUCE C., M.B. Edin., M.R.C.S. Eng., has been appointed Senior Resident Medical Officer to the Liverpool Hospital for Sick Children.

KISBY, GEO., L.R.C.P. Irel., L.F.P.S. Glasg., has been appointed Medical Officer for the Borough of Hyde, Cheshire, vice G. W. Sidebotham, resigned.

LLOYD, JORDAN, M.B., M.S. Durh., F.R.C.S. Eng., has been appointed an Honorary Consulting Surgeon to the Birmingham General Hospital, vice C. Pemberton, deceased.

MACFARLANE-AYLMER, A., L.R.C.P., L.R.C.S., has been appointed Honorary Medical Officer to the St. Mary's Hospital, Brighton, vice A. J. Richardson, deceased.

NICHOLSON, T. D., M.B., C.M. Edin., has been appointed Medical Officer for the Bolton and Thurnscoe Sanitary District.

PIRIE, W. R., M.B., C.M., M.A. Aberd., has been appointed Clinical Registrar in the Royal Infirmary, Aberdeen.

PRATT, ELDON, M.B. Lond., M.R.C.S., L.R.C.P., has been appointed Assistant Resident Medical Officer at the Cardiff Infirmary.

READ, A., L.D.S. R.C.S., has been appointed an Honorary Dental Surgeon to the Western Branch of the Brighton, Hove, and Preston Dispensary.

ROWLANDS, WM. H., L.R.C.P., M.R.C.S., has been appointed Resident Medical Officer to the Birmingham and Midland Free Hospital for Sick Children.

SHARPE, S. H., M.B., B.S. Dubl., has been appointed a Medical Officer for the Jervis-street Hospital, Dublin.

SKINNER, D. S., M.D., M.R.C.S., has been re-appointed Medical Officer of Health for Willesden.

STEEN, R. H., M.B. Lond., has been appointed Senior Assistant Medical Officer to the Chichester Asylum.

STOTT, HUGH, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for East Sussex, vice E. F. Fussell.

SWEETEN, B., M.B., C.M. Edin., has been appointed Medical Officer for the Mexborough Sanitary District.

SWORDER, E. G., M.B. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Royal Sea Bathing Infirmary, Margate.

THOMAS, D. W., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Senior Assistant House Surgeon to the Huddersfield Infirmary, vice M. B. James, resigned.

THOMAS, J. T., L.R.C.P. Irel., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Counties of Leicestershire and Rutland.

THORNE, A., L.R.C.P. Lond., M.R.C.S., has been appointed Surgical Registrar to the Central London Throat and Ear Hospital.

TEBBITT, E. R., L.D.S. R.C.S., has been appointed Honorary Dental Surgeon to the Middlesex Hospital Convalescent Home, Clacton-on-Sea.

TREADWELL, O. F. N., M.R.C.S., has been appointed Medical Officer of H.M. Convict Prison at Portland, vice G. H. Lilley.

WADDY, F. H., M.D. Glasg., has been appointed a Junior Resident Assistant Medical Officer for the Workhouse, Glossop.

YOUNG, C. W., L.R.C.P. Lond., M.R.C.S., has been appointed a House Surgeon to the Stockton Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £50, with board and washing.

BRADFORD INFIRMARY.—Junior House Surgeon, single. Salary £50 per annum, with board and residence.

BRENTFORD UNION.—Assistant Medical Officer for the New Infirmary, single. Salary £100 per annum, with furnished apartments in the Infirmary, rations, washing, &c. Applications to the Clerk to the Guardians, Isleworth, Middlesex.

BRISTOL GENERAL HOSPITAL.—Casualty Officer. Salary at the rate of £50 per annum, with board and lodging.

BUCKINGHAMSHIRE GENERAL INFIRMARY, Aylesbury.—Resident Surgeon and Apothecary, unmarried. Salary £80 for the first year, with an advance of £10 per annum until it amounts to £100, with board, lodging, washing, coals and candles, and furnished apartments.

BURY INFIRMARY, Lancashire.—Junior House Surgeon. Salary £60 per annum, with board, residence, and attendance.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Salary at the rate of £30 per annum, with board and residence.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer to act as Locum Tenens for two or three months during the summer. Salary £2 2s. per week, with furnished apartments and board.

COUNTY ASYLUM, Whittingham, Preston.—Locum Tenens for about six months. Two guineas a week.

COUNTY LUNATIC ASYLUM, Lancaster.—Holiday Assistant Medical Officer for five or six months. Salary 2 guineas per week, with board, &c.

DENTAL HOSPITAL OF LONDON MEDICAL SCHOOL.—Medical Tutor. Salary £40 a year.

Hosted by Google

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—House Physician for six months. Board, residence, &c., provided, and an honorarium of 15 guineas granted conditionally.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury, London.—House Surgeon to the Out-patients (non-resident) for six months. Salary 25 guineas.

LIVERPOOL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Honorary Assistant Physician.

LIVERPOOL NORTHERN HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance in the house.

MERCER'S HOSPITAL, Dublin.—Vacancies on the Surgical and Medical Staff.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—House Physician for six months. Salary at the rate of £60 per annum. Also Junior House Physician for six months. Board and lodging, including washing, provided. Applications to the Secretary, City Office, 27, Clement's-lane, Lombard-street, E.C.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Surgeon. Applications to the Secretary, Offices, 27, Clement's-lane, E.C.

ROYAL BERKSHIRE HOSPITAL, Reading.—House Surgeon. Salary £60 per annum, with board, lodging, and washing; also Assistant Medical Officer. Board, lodging, and washing provided, and an honorarium of £10 10s. awarded conditionally. The appointments will be for six months from Midsummer next.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, London.—Election of Professors and Lecturers.

ROYAL EAR HOSPITAL, Soho, London.—House Surgeon (non-resident) for six months. Honorarium 12 guineas.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—House Physician for six months. Salary at the rate of £40 per annum, with board, lodging, and washing.

ROYAL VICTORIA HOSPITAL, Bournemouth.—Ophthalmic Surgeon.

ST. PETER'S HOSPITAL, Henrietta-street, Covent-garden, London.—House Surgeon for six months. Salary at the rate of £100 a year, with board, lodging, and washing.

SUNDERLAND INFIRMARY.—House Surgeon. Salary £80, rising £10 annually up to £100, with board and residence. Also House Physician. Salary £80, rising £10 annually to £100, with board and residence.

SUSSEX COUNTY HOSPITAL, Brighton.—Assistant Physician.

WOOLWICH UNION.—Resident Assistant Medical Officer at the Infirmary, Plumstead, single. Salary £90 per annum, with apartments, rations, and washing. The appointment subject to deductions under the Poor-law Officers Superannuation Act. Applications to the Clerk to the Board, Union Offices, Woolwich.

Births, Marriages, and Deaths.

BIRTHS.

CARLESS.—On May 11th, at Welbeck-street, W., the wife of Albert Carless, M.S., F.R.C.S., of a son.

COX-MOORE.—On May 15th, the wife of Edward W. Cox-Moore, L.D.S., of Bloomsbury-square, W.C., and Sevenoaks, of a son.

CROKE.—On May 13th, at Welford House, Victoria-avenue, Harrogate, the wife of T. J. Croke, L.R.C.P. Irel., of a son.

DICKINSON.—On May 14th, at 33, Sloane-street, S.W., the wife of T. Vincent Dickinson, M.D., M.R.C.P. Lond., of a daughter.

FERGUSON.—On May 12th, at 51, Moffatt-road, Thornton Heath, Surrey, the wife of Robert J. Ferguson, M.D., of a son.

GORDON.—On May 16th, at Union-street, Aberdeen, the wife of John Gordon, M.D., of a daughter.

PITT.—On May 11th, at Portland-place, W., the wife of G. Newton Pitt, M.D., F.R.C.P., of a daughter.

TRAVERS-SMITH.—On May 15th, at Elmhurst, Copers Cope-road, Beckenham, the wife of V. H. Travers-Smith, M.D., of a son.

WILKINSON.—On May 16th, at Harcourt-road, Sheffield, the wife of George Wilkinson, B.A., F.R.C.S., of a daughter.

MARRIAGES.

COLLINS—NETTELFIELD.—On May 12th, at St. Augustine's, Kilburn, George Fletcher Collins, M.R.C.S., L.R.C.P., D.P.H., late Surgeon Royal Navy, to Fanny, only daughter of the late Richard Clark Nettelfield, of Stamford-hill.

WESLEY—WATKINSON.—On May 15th, at Hinde-street Chapel, Manchester-square, London, Frank William Wesley, M.D., B.S. Lond., of West Bridgford, Nottingham, to Florence, daughter of the Rev. W. L. Watkinson, of Brondesbury.

DEATHS.

BOYD.—On May 9th, at Westbourne-grove, Bayswater, Robert Boyd, M.D., aged 91 years.

KELLY.—On May 10th, at Raleigh-gardens, Brixton-hill, S.W., Frederick Kelly, F.R.C.S.

MAPLESON.—On May 12th, at Nottingham-place, W., Horsley Thomas Mapleson, M.R.C.S. Eng., L.S.A., aged 63 years.

ROBERTSON.—On May 18th, at Exmouth, Charles Alexander Lockhart Robertson, M.D. Cantab., F.R.C.P.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (26th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (27th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (29th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (25th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Mr. H. H. Clutton: (1) Case of Subclavian Aneurysm successfully treated by Ligature; (2) Case of Pharyngeal Abscess, Hæmorrhage, Ligature of Carotid Arteries.—Mr. W. Haward: On Irreducible Hernia.

WEDNESDAY (26th).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Annual Meeting and Conference. Discussion on the Influence of Light and other Forms of Radiant Energy on the Skin and Tissues, to be introduced by Dr. R. L. Bowles. Exhibition of Cases, Drawings, and Specimens.

FRIDAY (28th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Annual General Meeting. Election of Officers for Session 1897-1898. Mr. A. P. Gould: A Case of Pancreatic Calculus.—Dr. W. Ewart and Dr. H. D. Rolleston: A Case of Intra-Cardiac Thrombus, arising from the Fossa Ovalis, projecting through the Mitral Orifice, and giving rise to signs of Mitral Stenosis.—Dr. G. B. Hunt: A Case of Dissecting Aneurysm. Rupture into both Pleural Cavities.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (24th).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Sprue.

LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. McNeill Whistler: Demonstration of Cases.

TUESDAY (25th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Ringworm and Favus.

ROYAL INSTITUTION.—3 P.M. Dr. E. H. Starling: The Heart and its Work.

WEDNESDAY (26th).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Filariasis.

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Sources of Water.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Maguire: Physical Signs of Excavation of the Lungs.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: Surface Anatomy of the Lower Extremity.

BANQUET to be given to Lord Lister by his former House-Surgeons, Clerks, and Dressers at the Café Royal, Regent-street, at 7.30 P.M.

THURSDAY (27th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: On Sugar and other Reducing Substances found in the Urine of Disease.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. S. Mackenzie: Clinical Lecture.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Dr. S. Taylor: Surface Anatomy of the Head and Neck.

EAST LONDON HOSPITAL FOR CHILDREN.—3 P.M. Mr. L. A. Dunn: Tuberculous Inflammation of the Joints in Children.

FRIDAY (28th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Tuberculosis and Leprosy.

ROYAL INSTITUTION.—9 P.M. Prof. H. Moissan: The Isolation of Fluorine (with Experiments).

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

VICARIOUS RESPECT.

WE have received a copy of a Georgetown paper from which it would seem that the impending presence of the "Rev. Dr. John E. London, M.R.C.S.E., L.R.C.P.E., F.C.S., &c.," at the dinner to be given to Lord Lister by his junior colleagues has created a totally unnecessary excitement in the British Guiana Congregational Union. Mr. London will, we hope, point out to the somewhat fulsome gentlemen who have recently presented him with addresses that the occasion has been designed to honour Lord Lister, and not to honour his clinical clerks and dressers. The Union is wrong in supposing that the presence of Mr. London at the complimentary dinner to the President of the Royal Society has been sought because of any remarkable scientific lustre that would so accrue to a "great gathering of the learned medical fraternity." To allow such bosh to be circulated by the press without contradiction is to sanction gross advertisement at the expense indirectly of brother practitioners, the sooner the Rev. Mr. London repudiates the vicarious respect he has been receiving the more entirely will he be conforming with professional nicety.

C. M.—We do not recommend medical practitioners, specialists or others. The matter is one requiring no assistance from any specialist; our correspondent's usual medical attendant can advise him quite adequately.

THE ADULTERATION OF CONDENSED MILK.

DR. F. W. FORBES ROSS states, in the current number of *Treatment*, that a vegetable product, known commercially as the "tiger nut," is being largely imported for the purpose of adulterating the cheaper brands of condensed milk. It has the appearance of a rhizome, is no larger than the last joint of the little finger, resembles a diminutive root artichoke, and is not unpleasant to taste, the flavour being strongly suggestive of condensed milk.

"IS YOUR DOCTOR SOUND?"

THIS is the question at the head of a letter addressed to the readers of a little monthly paper called the *Animal's Friend*. The query does not refer to the medical man's constitution or morals—these are altogether subsidiary matters to the *Animal's Friend*—it refers to his attitude on the vivisection question. The writer, who dates his letter from a clergyman's house, makes a proposal which would, we are told, "be of great use," that the readers of the *Animal's Friend* should not "call in any medical man known to be a vivisectionist or a pro-vivisectionist, and if the doctor we have been employing is such" we should "dispense with his services, telling him the reason," and "summon another who is an anti-vivisectionist in his place." Knowledge, experience, and practical skill, observe, are to be quite secondary, and the issues of life and death are to be confided to anyone who will declare himself an anti-vivisectionist! If ever a writer has let his zeal run away with his pen (and the pronoun "his" includes "her"), it is the uncharitable idiot who has written propounding this question. But we wish him no worse than this, that, being laid upon a bed of sickness—a thing which happens even to those hysterical persons who believe that medical men experiment with animals out of wanton delight in torture—he may, for conscience' sake, dismiss an able attendant who understands his constitution and summon to his bedside a hysterical herbalist.

M.D.—All foreign practitioners in Brazil have to pass the examinations of the whole programme of studies adopted in the School of Medicine.

A REMARKABLE STUDENT.

WE quote the following from the *Indian Medical Record*:—

> "A student, named Borysik, has just passed the final examination at Warsaw University qualifying him to practise as a doctor of medicine in Russia. Borysik was born in 1822, and was educated at Suvalk Higher Grade School with a view to becoming a medical man. After passing his matriculation lack of funds prevented him from at once proceeding to the university, and he was compelled to work as a tutor for twenty years in order to save enough money to enable him to continue his studies. At the end of that time he presented himself at Warsaw Medical Academy, and passed the entrance examination with distinction. Before he could begin his studies the Polish rebellion of 1863 broke out, and Borysik, who was now forty-one years of age, threw himself into the movement with all the enthusiasm of a youthful revolutionist. The revolt was suppressed, and Borysik was exiled to Siberia, where for thirty-two years he underwent hard labour in the silver mines. In 1895 he received a free pardon and returned to Warsaw. In spite of his age and the hardships he had endured Borysik had lost none of his enthusiasm for medical work, and took up his studies where he had left them off in 1863. After a two years' course this remarkable man has now, at the age of seventy-five years, passed the final medical examination with honours and will begin to practise in Warsaw."

Mr. Lyon Falkener will find that we have commented adversely upon this identical circular.

A NEW TREATMENT FOR SPINAL CURVATURE.

DR. A. CHIPAULT, in the *Journal de Clinique et de Therapeutique Infantile*, April 29th, 1897, claims to have devised a new and effective form of back-splint for the treatment of spinal curvature. It consists of a plank of stout oak perforated by an aperture to allow of the passage of fæces and fixed on the back of the patient by means of bands at the level of the thorax, below the axillæ, above the pelvic bones, below the knees, and over the arch of the foot. Along the sides of the boards are two rails, upon which a cylinder is fixed sufficiently movable to allow two concave padded metallic plates to be adjusted where needed to the sides of the trunk of the body Once applied these are locked and thus retained in position. The apparatus is said to be easily constructed, cheap, and capable of adjustment to any bed. It can, when fitted with handles, be carried about without jolting the patient. The inventor advises its employment as a gentle and gradual corrective of the less extreme degree of Pott's curvature and of scoliosis, three metallic plates corresponding to the extremities of the concavity and to the convexity being used in the latter case. Manual pressure under chloroform is advised in some cases as a precursor to the splint, with a view to reduction at one time, if possible, of the curve. It is admitted, however, that the measures above described are useless in the more advanced cases associated with ankylosis. This new therapeutic method is still on its trial, and its practical value will probably continue for some time to be an unknown quantity. Its utility may possibly come to be confirmed by other observers besides its originator. If so, another gain will have been registered in the domain of surgery. Meanwhile, we must express a hope that operators will always be inspired by a wisely conservative regard for those important structures which are placed within the curved spine and contorted ribs.

"POPULUS VULT DECIPI."

A BORDEAUX medical journal is responsible for the following amusing if not instructive anecdote: "A certain individual who called himself Alexis, having been accused of signing prescriptions, besides otherwise trespassing on the prerogatives of the medical fraternity, the police commissary of the district—which is described as one of the most *selected* in the French capital—received instructions to investigate the charge and, should he find cause, arrest the delinquent. The official accordingly proceeded to the house where it was said that the medical canons were habitually violated, and a single glance sufficed to satisfy him that he had surprised his quarry *in flagrante delicto*. Magnificently installed in a suite of sumptuously-furnished apartments, with three spacious waiting-rooms filled to overflowing by well-dressed and evidently moneyed crowds of patients, the reputed quack submitted to the intrusion of his inauspicious visitor with dignified calmness. 'You will continue to admit callers,' he observed to his janitor as he was preparing to accompany the commissary to the police station, 'for I shall be back in a few minutes.' The officer did not actually smile when he heard this remark, for while on duty the smiles of an *agent de police* are as rare as black swans, but the case was as clear as daylight, and a close observer might have detected some indications of incredulous merriment near the corners of his mouth. 'You will do me a very great favour, sir,' said the accused when they had reached their destination, 'by according me a moment's private audience.' 'For what purpose?' inquired the man of law. 'There is something most important that I wish to communicate to your ear alone,' replied the other. The commissary, for all his apparent sternness, had an obliging disposition. 'Clear the room,' he exclaimed, and the pair were left free from witnesses. Upon this M. Alexis drew forth his pocket-book, and extracting therefrom a parchment diploma he spread the document out before the eyes of his astonished interlocutor. 'I beg of you,' he cried in imploring accents, 'not to betray me. I should lose every single patient I have got if they knew that I was a properly qualified practitioner. When first I obtained my degree I set up in the Faubourg Saint-Antoine, fixing a fine brass plate on my door and carrying out all details *secundum artem*, but in six months I had spent all my money and was starving. I consequently removed the plate, suppressed my surname, and established myself yonder as a bone-setter. Since then my affairs have gone on wheels, and I am in a fair way of making my fortune. I can advertise freely now, and knowing something about the business have succeeded in avoiding fatal mistakes. I implore you again to be merciful.' For a little while the commissary felt perplexed, but his doubts did not last long. When a *rebouteur* posed as a medical man it was his duty to pursue him, but the converse did not hold good. There was no law to prevent a practitioner turning bone-setter if he liked; and so M. Alexis, the qualified quack, continues to flourish."

We manage things better than this in England in some ways, though worse in others. With us the qualified quack would soon cease to enjoy any immunity conferred by his qualifications, as the General Medical Council would remove him from the register. But, alas, with us a quack requires no diplomas or degrees to protect him. He enjoys perfect freedom to swindle to his heart's content.

X. Y. Z.—In emergencies it has often to be done.

MEMENTOES OF GENERAL GRANT'S LAST ILLNESS.

"DR. GEORGE F. SHRADY, the editor of the *New York Medical Record*, who was Grant's medical attendant during his last illness as well as his close personal friend, has in his possession some interesting mementoes of the dead soldier, which," writes a correspondent, "I have been privileged to see. Amongst these are the hypodermic syringe made expressly for use in the General's treatment, and the pen with which he wrote the copy of most of his memoirs, and the original sheet of paper on which was written the 'famous Easter message' sent out by General Grant on the last Easter day of his life. This message was taken down in shorthand by Dr. Shrady from General Grant's dictation and runs as follows: 'Say that I am very comfortable. I am grateful for the sympathy that has been expressed for me. I wish you would say to the people that I am very much touched by, and very grateful for, the sympathy and interest manifested for me by my friends. You may also say—and by those who heretofore have not been regarded as such. Well, say this for me. I desire the goodwill of all, whether heretofore friends or not. Is that enough?' This letter was afterwards revised and sent out in the form of a bulletin, thus: General Grant has just awakened from a short nap and expresses himself as being very comfortable. He wishes it stated that he is very much touched by, and very grateful for, the sympathy and interest manifested for him by his friends and by those who have not heretofore been regarded as such. He says, 'I desire the goodwill of all, whether heretofore friends or not.'"

THE "LANOID" BANDAGE.

MR. T. I. WALLAS, of 491, Oxford-street, W., has forwarded to us a new kind of elastic bandage, which evidently possesses some novel and advantageous features. Unlike the ordinary pattern of elastic goods, it contains no indiarubber, but is a pure wool web bandage with "stretch" woven across the width, so that it yields only very little in the direction of its length, but can be easily pulled out to more than double its width, resuming its original form when released. It therefore adapts itself easily to the varying contour of the limb to which it may be applied, as in cases of varicose veins, rheumatism, sprains, &c., and is less liable to slip than ordinary roller bandages are. It is also easily washed. It is made in lengths of three yards and six yards, three inches wide for ordinary purposes and six inches wide for abdominal use.

Inquirer.—We cannot trace any such article. If our correspondent will consult THE LANCET of Aug. 1st, p. 309, Oct. 31st, p. 1248, and Dec. 12th, p. 1727, all in 1896, he may find what he is seeking.

"A MEDICAL OFFICER'S CHALLENGE."

WE quote the following from the *Birmingham Gazette* of May 12th:—

"On Wednesday night, at the Stone Urban Council meeting, the question of the medical officer's salary was re-considered. The council had re-appointed Mr. E. Fernie at an annual salary of £25, but the Local Government Board had written saying they did not consider this adequate remuneration for the discharge of the important duties.—A smart verbal passage-at-arms ensued between the medical officer and Councillor Smith. The latter urged that the outworkers in the local factories had decreased, whereas Mr. Fernie clearly proved that they had increased, and said that this was a ground on which he based his application for an increase of salary.—Councillor Smith continued to criticise, when the medical officer said, 'Well, I will make you a challenge, I can afford it. I'll give a guinea to the North Stafford Infirmary for every name wrong in the list (for 1896) if you'll give half-a-crown.' Councillor Smith did not accept the challenge. The Council passed a resolution increasing the medical officer's salary to £35 per annum."

Cantab.—It appears that there is no body "concerned in sending out medical men to the leper islands in the South Sea," neither has there been any recent literature published dealing with the condition of the lepers in these places. It is, of course, well known that leprosy is abundant in many of the islands, and it is feared that it is increasing in some of them.

A VERY QUESTIONABLE JUBILEE PROPOSAL.

A WRITER in the *Morning Post*, not content with the Prince of Wales's fund for hospitals and the Princess of Wales's fund for the poor in slums, proposes the establishment of another Jubilee hospital for poor gentlemen, and also a home for chronic invalids of this class—to wit, members of the professional classes. Surely this writer has a vein of humour in his composition and aims a sly blow at the overdone charity of the day. If this is not the true theory of his letter let us remind him that Jubilee hospitals have not been an unmixed success, and that we are a long way off the time when the classes he names require to be treated as if they were paupers. To read such letters we should think that all natural affection was dying out of the whole classes of the population hitherto independent, and that it was to be replaced by a new and doubtful charity.

M.B. (113, Grove-road, Walthamstow) would be glad to hear of an institution where a mentally deficient child could be received for treatment at a moderate cost.

During the week marked copies of the following newspapers have been received:—*Doncaster Chronicle, Liverpool Courier, Folkestone Chronicle, Durham Advertiser, Bristol Times, Brighton Gazette, Bradford Observer, Leicester Post, Accrington Observer, Chatham News, Architect, South Wales Daily News, Kentish Express, Barnet Press, Times of India, Pioneer Mail, Manchester Guardian, Builder, Derby Express, Birmingham Post, Bristol Mercury, Huddersfield Chronicle, East Anglian Daily Times, Wigan Examiner, Liverpool Daily Post, Newcastle Chronicle, Leeds Mercury, Scotsman, Sussex Daily News, Eastern Morning News, Sheffield Telegraph, Yorkshire Post, Citizen, Sanitary Record, Glasgow Herald, Worthing Intelligencer, Mining Journal, Reading Mercury, Local Government Chronicle, Hertfordshire Mercury, Weekly Free Press and Aberdeen Herald, Gazette (Montreal), Family Herald and Weekly Star (Montreal), City Press, Daily Free Press (Easton, Pa.), Public Health Journal (New York), Citizen (Gloucester), Surrey Advertiser, Local Government Journal, Banffshire Journal, Penrith Observer, Inverness Courier, Perth Constitutional, Falkirk Herald, Clifton Society, Nairnshire Telegraph, Isle of Man Daily Times, The Bailie, Midland Evening News, West Middlesex Herald, City of Ely Standard, Long Eaton Pioneer, Gloucester Journal Prescot Reporter, &c., &c.*

'Tabloids' as Therapeutic Agents

BLAUD PILL 'TABLOIDS.'

A SERIES of 65 clinical trials undertaken at the National Hospital for Diseases of the Heart, Soho Square, proved that under equal conditions the administration of Blaud Pill 'Tabloids' caused an increase in Haemoglobin of 1·2 per cent. a day, whilst in the case of all other preparations used it never exceeded 0·5 per cent.

COMPOUND BROMIDE 'TABLOIDS.'

"Compound Bromide 'Tabloids' are an admirable means of continuous bromide treatment. Being composed of the salts of sodium, strontium and ammonium they are less depressing than the potassium salt."—*Quarterly Medical Journal, April, 1897.*

SODA-MINT 'TABLOIDS.'

Soda-Mint 'Tabloids' form an active and agreeable neutralising compound. One to four 'tabloids' may be given in a draught of water, or allowed to dissolve slowly in the mouth.

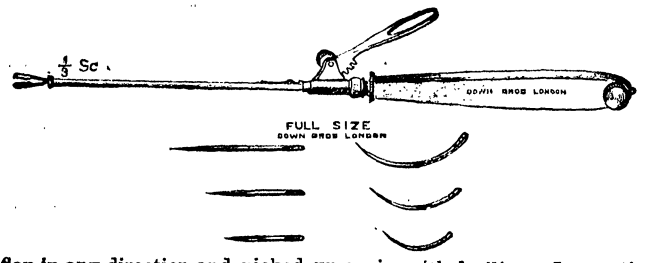
DOWN BROS.' SPECIALITIES.

METAL HOSPITAL INHALER

(Suggested by Dr. SILK, Anæsthetist to King's College, Hospital, &c.).

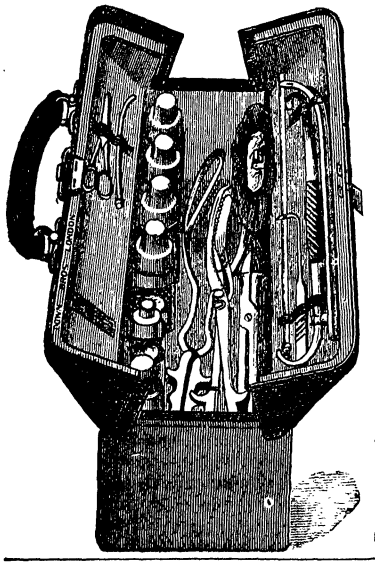


This Inhaler has been specially designed to meet the demands of busy Hospital Work, and will be found to be more easily sterilised in accordance with the advanced theories of aseptic surgery than the ordinary forms in use. The general shape is that of the well-known Rendle's mask, but the dome-shaped top of the latter is inverted so as to form a perforated cup, through which the sponge can, if necessary, be fed with the liquid. This top is hinged to the body of the Inhaler to allow the sponge to be introduced in the first instance. Another distinctive feature is the metal diaphragm, set at an angle, and designed to prevent the superfluous liquid from running on to the face—a radical defect of many inhalers unless in skilled and careful hands. To further ensure that the sponge shall not slip on to the face, a wire guard is fixed across the opening in the diaphragm. It is intended primarily for the A.C.E. Mixture, or it may be used to maintain the anæsthesia with ether: it if not intended for pure chloroform. Being made of metal, the Inhaler can be kept perfectly clean with the least possible trouble; and it does not become sodden or get out of shape, as is the case with leather inhalers. **Price, complete, £1 2s. 6d.**

ALCOCK'S PORTABLE LIGATURE HOLDER.

(Suggested by Dr. S. KING ALCOCK of Bursiem.)

"The illustration represents a new Ligature Box, which has been designed to secure the advantages of compactness and absolute water-tightness, which hitherto have not been combined in any one apparatus. The trough is made of earthenware, and fitted with three reels of the same material. The cover consists of a sheet of detachable plate glass, a narrow layer of indiarubber bordering the under-surface. When the reels are in position and the trough filled with solution, the cover is clamped down by means of the screws. The ends of the ligatures can be freely drawn out between the rubber lining and the edge of the trough until the reels are completely exhausted. The apparatus will be found useful, especially for private use."—THE SCALPEL, January, 1896. **Price 10/6 each.**



LANE'S CLEFT PALATE NEEDLE HOLDER (Registered) and NEEDLES.

(Suggested by Mr. ARBUTHNOT LANE, F.R.C.S.).

This Instrument has been specially designed to operate on Cleft Palate in Young Children (as soon after the first month as possible). It consists of a mechanism by which a needle can be held securely, passed through a flap in any direction and picked up again with facility. In practical use the precision and despatch obtained by the use of this instrument leave nothing to be desired. The Needles are very small, and are of two patterns—straight and full curved—varying in length from three-eighths to five-eighths of an inch. This form of Needle Holder is equally useful in closing an incision in the common bile-duct, or a fistulous opening in the bladder or rectum.

Price each 25/-. In Case, with Metal Needle Box, £1 13s. 6d. Needles 2/6 per dozen.

DOWN BROS'. NEW "DESIDERATUM" MIDWIFERY BAGS.

No. 1 size, containing Barnes' Midwifery Forceps with Simpson's handles, Simpson's Craniotomy Forceps, Denman's Perforator, Blunt Hook and Crochet, and Frænum Scissors (all nickel-plated), Celluloid Female Catheter, three stoppered Bottles in boxwood cases, Tube Boric Jelly, Bottle Mercurial Pellets, and spring stoppered Drop Bottle. Complete **£5 11 6**

No. 2 size, Aseptic, containing Barnes' Midwifery Forceps with metal Simpson's handles, Simpson's improved Craniotomy Forceps with metal handles, solid forged Blunt Hook and Crochet, Denman's Perforator, Frænum Scissors (all nickel-plated), Celluloid Female Catheter, Budin's Tube for Washing out Uterus, Galabin's Bougie for Inducing Premature Labour, Skinner's Chloroform Mask, Rodman's Drop Bottle, four 2-oz. stoppered Bottles in boxwood cases, Tube Boric Jelly, Bottle Mercurial Pellets, Bottle Carbolised Silk. Complete **£8 0 0**

USEFUL ADDITIONS:—Cephalotribe, Transfusion Apparatus, Barnes' Hydrostatic Dilators.

ABSTRACT OF

Lectures

ON

DISEASES OF THE GALL-BLADDER AND BILE-DUCTS.[1]

Delivered at the Royal College of Surgeons of England on March 8th, 10th, and 12th, 1897,

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LECTURE I.

Delivered on March 8th.

MR. PRESIDENT AND GENTLEMEN,—Had time permitted the anatomy of the gall-bladder and bile-ducts would have formed a subject of sufficient interest for my first lecture but the number and importance of the matters I propose to consider clearly demonstrate this to be an impossibility, some of the more important anatomical points, however, I must not omit.

Congenital malformations.—There is apparently no part of the biliary apparatus, except the liver, which may not be absent. While it is not to be wondered at in the case of the gall-bladder and cystic duct since they are normally wanting in certain animals and are frequently obliterated by disease in the human subject, it affords serious food for thought to find that life has been possible for six months where even the hepatic and common ducts are represented by mere fibrous cords. Hour-glass shaped gall bladder is probably not uncommon, for though I have found only one specimen in the museums, and that at Middlesex Hospital, I have myself operated on two cases in which the distal part of the gall-bladder contained calculi and was connected with the gall-bladder proper by a narrow neck. On numerous occasions I have found the ordinary position of the gall-bladder vacant, and the shrunken viscus to be situated near the transverse fissure of the liver under cover of the pylorus, with the transverse colon adherent over it. On two occasions I have found the gall-bladder, containing gall-stones, displaced very much to the right; in one instance the liver was almost bifid, the left lobe predominating and pushing the right, and with it the gall-bladder, so far round as to make it project into the lumbar region. In palpating the common duct for gall-stones the surgeon frequently feels several more or less hard nodules within the free border of the lesser omentum, by the side or in front of the common duct, and unless it be borne in mind that three or four lymphatic glands normally exist here they may be apt to mislead, especially as they are not unusually considerably enlarged where there is gall-stone irritation. The large peritoneal pouch bounded above by the right lobe of the liver, below by the ascending layer of the transverse meso-colon covering the duodenum internally, externally by the peritoneum lining the parietes, posteriorly by the ascending meso-colon covering the kidney, and internally by the peritoneum covering the spine, has been long recognised, but perhaps not sufficiently appreciated, in gall-bladder surgery. Mr. Rutherford Morison drew attention to it in 1894.[2] He places such reliance on the ease and safety with which it can be drained that he does not advocate much time being spent in suturing incisions in the gall-bladder or bile-ducts. It is interesting to note that it is capable of holding nearly a pint of fluid before it overflows into the general peritoneal cavity. A deformity of the liver, congenital or acquired, may at times lead to a difficulty in diagnosis, or in treatment. I refer to a tongue-shaped prolongation of the right lobe, which may project below the costal margin for several inches and simulate a tumour of the liver or an enlarged gall-bladder. Professor Riedel has described it, and the projection is sometimes known as Riedel's lobe. It is said to be uniformly due to cholelithiasis, but in one case at least in my experience i was not associated with gall-stones.

I propose to consider my subject under four headings: (1) inflammatory affections; (2) tumours; (3) the surgical treatment of gall-stones; and (4) intestinal obstruction dependent on gall-stones.

Catarrh of the gall-bladder and bile-ducts.—The larger bile-ducts and the gall-bladder, being lined with mucous membrane, are, like other mucous passages, subject to catarrh, which may be acute or chronic. As, however, acute and chronic catarrhal jaundice are subjects of medical rather than surgical interest, I can only briefly consider them on account of want of time. Acute catarrh is supposed to give rise to the evanescent form of icterus known as catarrhal jaundice, which, more frequently occurring in young persons, usually comes on as a sequence of dyspepsia or as a result of exposure to cold, and is ordinarily unaccompanied by pain or serious illness. When it is borne in mind that the bile-ducts have only a limited calibre, that the mucous lining is capable of swelling so as to occlude the passage, and that the secretion of bile takes place under very low blood tension (according to Naunyn 110 to 220 mm. of water), and is, therefore, arrested by slight backward pressure, it is easy to comprehend how catarrh in this situation should lead to jaundice, though absolute proof of the correctness of the theory is wanting, since simple catarrhal jaundice furnishes no post-mortem subjects. With regard to its etiology, an extension from the duodenum is probably the usual cause of acute catarrhal jaundice, but exposure to cold, extension of inflammation from the liver, carcinoma of the liver, gall-stones, hydatids, pneumonia, and other acute inflammations must be mentioned as causes of catarrh, direct or indirect. Dr. Murchison gives gout and syphilis as causes, and Dr. Fagge includes under this heading jaundice due to fright and that occurring in epidemics. Although it is well known that in cancer of the liver jaundice is a very variable sign, it is not always recognised that the icterus is at times dependent on the associated catarrh, which may be relieved by treatment, though the original disease persists.

Chronic cholangitis or chronic catarrh of the bile-ducts may be simply a sequel to the acute form, and may then give rise to a more or less persistent jaundice leading to a suspicion of serious organic disease. Although there are dyspeptic symptoms due to the associated gastro-intestinal catarrh, with jaundice and some loss of weight, the retention of strength and the absence of serious sequelæ, such as ascites and hæmorrhage, generally enable a good prognosis to be given, especially as the symptoms usually yield to proper treatment. Catarrh of the bile-ducts probably always accompanies jaundice from whatever cause, and as Dr. Moxon has pointed out, a colourless mucus is always found in the bile-ducts when an obstruction in the common duct is complete. A search through the pathological records of Guy's Hospital for twenty years failed to discover any exception to this rule. When the obstruction is only partial, the mucus may be well charged with bile, as the backward pressure is not sufficient to stop the secretion and pouring out of bile into the ducts. Gall-stones are probably always accompanied by catarrh, which, giving rise to the formation of thick ropy mucus, leads to attacks of pain when passing, and it seems not unlikely that some of the minor seizures of pain are of this nature. Although the jaundice in cholelithiasis is usually produced by a gall-stone obstructing the common or hepatic ducts, I am convinced that in many cases jaundice is present when the concretion is in the gall-bladder or in the cystic duct, the obstruction to the flow of bile being caused by an inflammatory swelling of the mucous membrane of the bile channels caused by extension from the seat of obstruction. Riedel[3] states that about two-fifths of the causes of jaundice in cholelithiasis arise in this way. The treatment of chronic catarrhal jaundice is at first medical, and if the disease prove obstinate a course at Harrogate or Carlsbad will be likely to do good if the ailment be functional, but that failing, the question of some organic cause that may be removable by surgical treatment should be considered. Dr. Thudichum, describes a catarrh of the finest ramifications of the bile ducts which causes their lining to be shed in the shape of biliary casts. He considers that these often form the nucleus of gall-stones where the catarrh is associated with decomposition of bile. This has been termed by Meckel "lithiatic catarrh"; perhaps a better term is desquamating anglo-cholitis or stone-forming catarrh

[1] Mr. Mayo Robson circulated at his lectures a table of 170 operations on the gall-bladder and bile ducts, performed by himself, in which the particulars of each case were recorded. We regret that want of space prevents its reproduction in our columns.

[2] Brit. Med. Journ., March 3rd, 1894.

Hosted by Google

of the bile-ducts. It doubtless has great etiological importance in reference to gallstones, especially when associated with decomposition due to the presence of micro-organism in the stagnant fluid in the ducts.

Catarrhal cholecystitis, or chronic catarrh of the gall-bladder without jaundice, forms a distinct and definite disease, and I have seen several cases in which cholelithiasis has been diagnosed and operation advised; but where neither the gall-bladder nor ducts contained anything firmer than thick, ropy mucus, which was apparently the cause of painful contractions of the gall-bladder simulating gall-stone seizures. In one case of this kind, in a woman, aged sixty years, on whom I operated with Mr. Clifton of Sheffield, the gall-bladder contained bile mixed with thick, ropy mucus. There were no other signs of disease, but the gall-bladder was very large and pouched and the mucous membrane thickened. Cholecystotomy was performed and the drainage was continued for a fortnight, after which the wound was allowed to close. The patient after two years continues well. Dr. Byron Robinson[4] describes a case in which there were attacks of pain like cholelithic seizures, which he thought were dependent on kinking of the common bile duct producing obstruction to the flow of bile into the duodenum, but which I think may be more easily explained on the hypothesis that it was a case of chronic catarrhal cholecystitis. It came on six months after the removal of gall-stones from the gall-bladder. On opening the abdomen the gall-bladder, though free from stones, was found to be considerably enlarged, although the duct was patent, as proved by syringing water through it into the duodenum. Cholecystotomy resulted in recovery. In these cases the gall-bladder is usually distended, but it rarely forms a distinct tumour, and there is an absence of pain on pressure over it. Unless gall-stones have been present at some time there are usually no adhesions of the gall-bladder or ducts to the neighbouring viscera, proving that the inflammation has not extended through to the peritoneal coat, as it usually does when dependent on cholelithiasis. The benefit derived from a systematic course of treatment in these cases renders it advisable that medical should always precede surgical treatment. The diagnosis from cholelithiasis may usually be made by observing that the attacks are less severe and less prolonged than in true gall-stone seizures; that no gall-stones are found in the evacuations after an attack; that jaundice seldom supervenes, and, if it does, is only very slight; that there is no tenderness on pressure between the ninth costal cartilage and the umbilicus; and that the affection will usually completely yield to treatment. In chronic catarrh of the gall-bladder regular exercise, massage over the hepatic region, the avoidance of anything tight around the waist, careful regulation of the diet, and the judicious employment of saline aperients should be in all cases adopted. The spasmodic attacks may require the administration of a sedative, and in some cases, like those referred to, nothing short of a subcutaneous injection of morphia will do any good. If after a few weeks of general treatment the symptoms are not relieved the case will probably be thought to be one of gall-stones, and operative treatment will be considered advisable. If the gall-bladder and ducts be found free from gall-stones cholecystotomy and drainage should nevertheless be performed, and it will be found useful after the third day to syringe gently a little warm water through the drainage-tube daily so as to wash out the ducts, and after a fortnight or more the tube may be left out and the wound allowed to close. General treatment directed to the cause should be continued for some time afterwards. My proposal, in fact, is to treat obstinate catarrh of the gall-bladder as we do catarrh of the urinary bladder—first by medical and general remedies, and, those failing, to secure physiological rest by means of drainage.

Suppurative inflammation of the bile passages.—At first sight suppurative inflammation of the gall-bladder and bile ducts would seem to be capable of description under one heading, but the subject is by no means as simple as it would appear. Simple empyema or suppurative catarrh of the gall-bladder differs *in toto* from phlegmonous cholecystitis, which, however, is also associated with pus in the gall-bladder, but which is one of the most fatal of diseases if not operated on expeditiously, as not only is there a tendency to gangrene, but to a rapidly spreading lethal peritonitis. The different clinical characters of suppurative inflammation can probably be accounted for by the presence or absence of certain organisms, and although the bacteriology of this region is still in its infancy sufficient good work has been done to make a review of it well worth considering. It has been supposed that the bile is an antiseptic fluid which tends to prevent decomposition in the alimentary canal, but in a series of observations which I published some years ago[5] on a case of biliary fistula I found that the absence of bile from the intestine of a woman during a period of fifteen months did not lead to any irregular fermentative process, showing that the alleged antiseptic effect of bile on the fæces is probably imaginary. Normal bile is, however, generally sterile. This was proved by Netter in 1884,[6] who experimented on dogs, and the fact has been confirmed by Gilbert and Girode,[7] and later by Naunyn[8] who found it sterile in two cases within a few hours of death. Frequent inoculative experiments on animals have confirmed these observations, thus explaining a well-known fact that in many cases bile has been extensively poured out into the peritoneal cavity without setting up peritonitis; but in disease of the gall-bladder or bile-ducts the bile is seldom or never sterile, and is capable of producing severe peritonitis. Bloch has demonstrated that the bile in cases of disease of the gall-bladder or bile-ducts always contains micro-organisms, hence he thinks it advisable to perform cholecystotomy in two stages, in order to avoid soiling the peritoneum and producing infective peritonitis. When the flow of bile along the ducts is arrested, micro-organisms often invade the gall-bladder either from the blood or the intestine. Charcot and Gombault[9] demonstrated the presence of organisms within it after ligaturing the common duct in dogs. This was confirmed by Netter in 1886,[10] who found that twenty-four hours after aseptic ligature of the common duct in dogs, organisms, both staphylococcus and bacillus coli communis, could be cultivated from the bile. The bacillus coli communis exists normally in the human body, and is said to be the most abundant and most constant of the bacteria found in man in health. At one time, as shown by Escherich,[11] it may act as an ordinary pyogenic organism producing local abscesses, at another as an active pathogenic germ producing fatal septicæmia. Mr. C. B. Lockwood[12] found streptococci and other organisms, but no amœbæ coli in an empyema of the gall-bladder. Netter[13] found staphylococci and streptococci present in pathological human bile, and Martin,[14] Gilbert and Girode[15] and Bouchard[16] have found the bacillus coli communis in the bile in cases of inflammation of the biliary passages. In acute or phlegmonous cholecystitis the walls of the gall-bladder are swollen and œdematous, and may be infiltrated with pus. In three out of five of such cases Naunyn found the bacillus coli communis in the pus. Barbacci and others have shown that peritoneal sepsis may occur without perforation of the gut. The spread of infection through the walls of the gall-bladder can readily be explained, on the same hypothesis, showing how virulent peritonitis may arise in these cases, though there be no perforation. Gilbert and Girode[17] found typhoid baccilli in the pus from a case of empyema of the gall-bladder which came on as a sequence of enteric fever. Gilbert and Dominici[18] also assert that they produced suppuration in the gall-bladder and liver of rabbits by injecting a culture of typhoid bacilli into the common duct. These biological facts are borne out by the clinical observations of Dr. Murchison and of Dr. Hale White, who have found evidence of inflammation and ulceration in the gall-bladder in well-marked and fatal cases of typhoid fever, there being no other cause than the specific disease to account for the trouble. Chiari[19] investigated systematically a series of 22 cases of typhoid fever. With the exception of 3 cases, one of which was in the infiltrating and two were in the necrotic stage, he obtained typhoid bacilli invariably out of the gall-bladder, and in 15 cases they were obtained in pure culture. In 13 of the 19 cases in which a positive result was obtained

there was inflammation of the gall-bladder with small-celled infiltration, œdema, and hyperæmia. In all 22 cases the diagnosis of typhoid fever was confirmed by cultivations from the spleen, mesenteric glands, or liver, or from the larger bile-ducts. How do they reach the gall-bladder? There are three possibilities; either they enter by the bile-ducts, or from the blood, or directly through the wall of the gall-bladder. The last mentioned manner must be very exceptional. Their entrance from the blood has been apparently disproved, and it is therefore probable that they enter by the bile-ducts. There is no doubt that the bacilli multiply in the gall-bladder, and it is possible that they may be responsible for post-typhoidal cholecystitis, for gall-stones, and also for relapses of the disease.

Simple empyema.—Suppurative catarrh or simple empyema of the gall-bladder or suppurative cholecystitis is as a rule associated with gall-stones, but tumours of the bile-ducts, typhoid and other fevers, and other unexplained conditions may also be the predisposing factors, though infection by pyogenic organisms is probably in every case the true exciting cause. Empyema of the gall-bladder must always be looked on as a serious affection, both on account of its causes and its sequelæ, but from a clinical standpoint there is one form which is decidedly less serious than the other. The less serious I prefer to discuss first under the term simple empyema of the gall-bladder; the more serious form I shall consider as a distinct and special disease under the name of phlegmonous cholecystitis. When we bear in mind Charcot's and Gombault's experiments on ligature of the common duct in dogs just referred to, the wonder is that all impacted gall-stones are not associated with empyema; yet such is not the case, and it is only in a certain small percentage that the catarrh passes on to suppuration. When there is an obstruction or any irritation in the cystic duct a simple empyema may result, but when the obstruction is in the common duct it may be associated with suppurative cholangitis, the former being a local suppurative process, the latter an extremely serious disease, rapidly followed by general symptoms, and unless treated by operation often ending fatally. In simple empyema the symptoms will at first depend on the cause; and as this is, in the great majority of cases, cholelithiasis (Courvoisier found empyema to be caused by gall-stones in forty-one out of fifty-five cases) there will be the usual history of gall-stone seizures, followed by a swelling under the right lobe of the liver, and by a continued instead of an intermittent pain. At first the constitutional symptoms may be only slightly marked, and there may be no increase of temperature, though in other cases rigors or chills with fever will point to the formation of pus. The loss of appetite, fever, and general malaise usually lead to loss of flesh and weight. As a rule there is no jaundice or only a slight icteric tinge dependent on associated catarrh of the bile-ducts. Tenderness is nearly always present in consequence of local adhesive peritonitis. The tumour, if seen at an early stage, will move with respiration, descending with the liver and being felt as a rounded swelling. After a time the swelling may become more diffused and general, and the movements during respiration will be less marked or may cease owing to the inflammation extending to the abdominal walls. If the suppuration extends beyond the gall-bladder the pus may make its way through the parietes, and an abscess may form under the ribs. The pus usually, however, selects a more tortuous passage, and following the suspensory ligament of the liver it reaches the umbilicus. The abscess may even burst at a distance from its origin—for instance, over the pubes or over the cæcum. There are generally peritoneal adhesions which prevent extravasation into the general peritoneal cavity, but the pus may make its way into neighbouring organs. If we bear in mind the pouch of peritoneum I have described, it is not to be wondered at that a collection of pus should at times form in that region resembling a peri-renal abscess, though inside the peritoneum and limited by adhesions. Needless to say, an abscess of the gall-bladder only requires treating on general surgical principles by opening and drainage, but at the same time the cause must not be overlooked, as it may often be removed at the same time that the abscess is evacuated. Where the pus is in the gall-bladder cholecystostomy will be advisable. After exposing the gall-bladder it will be wise to aspirate before opening it, in order to avoid soiling the tissues with pus. The walls of the gall-bladder may be found so rotten as to be incapable of holding sutures, or, as in a case lately recorded by Dr. Willie Meyer, there may be small abscesses in the inflamed wall of the gall-bladder itself. In such cases cholecystectomy may be required. In two cases of empyema of the gall-bladder I simply evacuated the pus, removed the gall-stones, and packed the cavity with iodoform gauze, and although the peritoneal cavity was widely opened no harm resulted, as a lymph barrier was soon thrown out limiting the only partly disinfected area. In abscess due to empyema of the gall-bladder forming at a distance from the seat of origin, it may be wise at first simply to open and drain the abscess and on some future occasion to perform cholecystostomy. In some cases of empyema the patient may not be in a fit condition to bear a prolonged operation, and it may, therefore, be wiser to perform a simple cholecystostomy and to defer the removal of the cause until an examination of the discharge shows it to be sterile, or nearly so.

Acute phlegmonous cholecystitis and gangrene of the gall-bladder.—Acute or phlegmonous inflammation of the gall-bladder was described by Courvoisier in 1890, under the name of acute progressive empyema of the gall-bladder, and he states that it usually terminates fatally in a few days from diffuse peritonitis. Only seven cases are recorded in Courvoisier's statistics. Potain[20] also mentions that in addition to the ordinary variety of empyema of the gall-bladder there is a very grave condition of acute empyema, which is followed by rapid peritonitis and death. In one case which he describes death occurred on the second day after the onset of the attack, and although there was no perforation of the walls of the viscus infection had spread through the coats to the general peritoneal cavity. Osler[21] refers to it as an extremely rare disease. As to the symptoms, although the condition is usually associated with gall-stones, acute cholecystitis may arise quite independently—in this way resembling appendicitis, which may occur without the presence of foreign bodies. Typhoid fever and typhus fever, cholera, malaria, sepsis after operation, puerperal fever, and other unknown conditions may give rise to it. Whatever be the cause, the disease usually manifests itself somewhat suddenly with pain on the right side of the abdomen, rapidly becoming general. A rapid and feeble pulse, quick thoracic breathing, fever, intense depression, marked tenderness on pressure, especially over the right side of the abdomen, rapidly developing tympanites, persistent vomiting, and an extremely anxious expression of countenance are usually present. The acute peritonitis, which is significant of the disease, may be localised at first, but later becomes general. Jaundice may or may not be present, and although an elevation of temperature is usual, it is by no means constant and affords only slight assistance in the diagnosis or prognosis. If the disease be of the very acute or gangrenous variety death speedily occurs, but if of the sub-acute form an abscess may develop around the gall-bladder and the peritonitis may become localised, the disease then resembling a perityphlitic abscess in its course.

Diagnosis.—The diagnosis of phlegmonous cholecystitis practically resolves itself into the diagnosis of the cause of acute peritonitis, starting on the right side of the abdomen. Although this may be due to perforation of the stomach at or near the pylorus, to perforation of the duodenum or the ascending colon, to perforation of the gall-bladder or the bile-ducts, and to other such-like peritoneal catastrophes, the chief affection for which it is likely to be mistaken is acute appendicitis. In appendicitis the pain begins at a lower point in the abdomen and passes towards the umbilicus, whereas in gall-bladder trouble it begins below the right costal margin and passes towards the epigastrium and back to the right scapular region. In all gall-bladder inflammations there is almost invariably a tender spot a little above and to the right of the umbilicus, or, to be more exact, at the junction of the upper two-thirds with the lower third of a line drawn from the ninth rib to the umbilicus. In appendicitis there is in the same way a tender spot at the junction of the outer third with the inner two-thirds of a line drawn from the umbilicus to the anterior superior spine of the ilium, known as McBurney's point. The symptoms of acute peritonitis and paralytic obstruction of the bowels are common to both. Fortunately, the treatment by exploratory incision is appropriate to the various conditions mentioned, so that no serious error is likely to arise in case of mistaken diagnosis.

Treatment.—Relief of pain by subcutaneous injections of

morphia, will probably always be demanded as a primary measure, and as it is clearly impossible to make a diagnosis of the serious condition within the first few hours, warm applications, absolute rest, the stoppage of feeding by the mouth except in small quantities, and the relief of symptoms as they arise must be followed out; but as soon as the diagnosis of phlegmonous cholecystitis can be established, and it is found that the patient is getting worse, an exploratory incision should be made and the gall-bladder incised and drained, the cause if found being removed. If, however, gangrene be discovered the gall-bladder should be removed, the indications for that measure being as distinct as in the case of a gangrenous vermiform appendix. If, in the subacute cases the inflammation becomes localised and a swelling with tenderness be found beneath the right costal margin, incision and drainage are called for, when at the same time cholecystotomy may be performed, and if gall-stones be present in the gall-bladder or ducts they may be removed. If the patient be too ill to bear a prolonged operation the latter procedure may be left to a subsequent occasion.

Gangrene of the gall-bladder is probably only an extreme degree of phlegmonous cholecystitis. The comparative frequency of gangrene in the vermiform appendix might lead one to suppose that gangrenous inflammation of the gall-bladder would not be uncommon, yet it is extremely rare, and, so far as I know, the case reported by Dr. L. W. Hotchkiss is the only one recently recorded. In order to explain the occurrence of gangrene three factors have to be borne in mind: (*a*) Thrombosis of the nutrient vessels; (*b*) bacterial infection; and (*c*) absence of drainage, and therefore tension. The two latter are present in both gall-bladder and appendix inflammation, but the first factor is more frequent in the vermiform appendix, which is only supplied by one nutrient artery, whereas the gall-bladder has a very free blood supply, not only through the branches of the cystic artery, but also through their anastomosis with the hepatic vessels, where the gall-bladder is fixed to the liver In Dr. Hotchkiss's case there was an abnormal circular constriction of the gall-bladder with lymph infiltration, which was apparently sufficient to cut off the blood supply from the extremity of the gall-bladder.

Infective and suppurative cholangitis.—Infective and suppurative cholangitis, or suppurative catarrh of the bile-ducts, are subjects of deep interest to the surgeon, since the medical treatment of these ailments is somewhat limited. Cholelithiasis is by far the most common cause, and in the museums there are several cases illustrating it. Other causes are hydatid disease, malignant disease of the liver, and typhoid fever. The causes mentioned may be truly termed predisposing, since the true exciting cause is the presence of pyogenic organisms. The bacillus coli communis produces an exudative inflammation of the ducts, and may actually cause abscesses within the walls of the biliary passages. Hepatitis and liver abscess frequently follow on cholangitis, and this is usually followed by general and fatal infection of the system. *Endocarditis* is at times set up, and as it has been known to follow cholangitis without hepatitis,[22] and cholangitis without abscess, this cause should never be lost sight of in any case of ulcerative endocarditis. The bacillus in these cases in the vegetations on the inflamed endocardium has been found to be identical with the one found in the bile. As to the symptoms in suppurative cholangitis there is progressive enlargement of the whole liver, which may descend as low as the umbilicus, the swelling being uniform, smooth, and tender to pressure. If the cause be in the common duct, and the gall-bladder has not previously become contracted, there will be the additional enlargement caused by its distension; but when contraction has taken place, and also when the obstruction is in the hepatic duct, there will be an absence of the signs of empyema of the gall-bladder. Pain may be entirely absent, as in one case on which I operated, where the disease was dependent on cancer of the common duct; but where it is dependent on gall-stones the pain may be severe and paroxysmal, each attack being accompanied by ague-like seizures and an intensification of the jaundice. Jaundice is always present and is usually both persistent and intense. Continued fever, with occasional rigors and profuse perspiration, forms a feature of the disease, and with this there is rapid loss of flesh and strength. Pneumonia and pleurisy, ending in empyema, are sufficiently common to be characterised as distinct concomitants of suppurative cholangitis. The disease is an extremely serious one and may prove fatal, though if the cause can be removed at an early stage recovery may occur. If the disease be less acute the inflammation may concentrate itself in some part of the liver leading to abscess, which may form a distinct tender swelling and give rise to the usual symptoms and signs of hepatic abscess. As to treatment, unless evacuation and drainage of the infected contents of the bile passages can be accomplished treatment is practically useless. Cholecystotomy should, therefore, be performed, and free drainage established and continued until the bile is sterile or nearly so. Although good results cannot be expected in all cases, an amelioration of the symptoms may be looked for in a fair proportion, and complete relief in others. If a localised abscess be discovered in the liver it should be opened and drained, and though it is scarcely to be expected that operation can be always successful in these serious cases the chances of permanent benefit is worth snatching at, even in the most desperate conditions. Of general means, warm applications to the hepatic regions, an initial mercurial purge followed by milder laxatives, intestinal antisepsis by administering bismuth and salol, the relief of pain by sedatives if called for, and the treatment of symptoms as they arise, will afford some amelioration, though they will probably only give temporary relief. Although surgeons have been performing cholecystostomy for infective cholecystitis and for gall-stones producing infective cholangitis for some years, I think it is only right to give the chief credit of specially operating for cholangitis to M. Terrier. He writes in the *Revue de Chirurgie* for 1895, p. 966:—"Thanks to the opening in the gall-bladder a certain number of important therapeutic results follow: (1) the septic contents of the gall-bladder are evacuated; (2) calculi which are most frequently present there are removed; (3) the other biliary passages more or less obstructed, either by calculi or by swelling of their walls, are rendered as free as possible; (4) the septic bile is allowed to escape and mechanically washes out the lower passages carrying away through the drainage-tube many of the infectious ailments; (5) the relief of pressure prevents absorption of the septic elements; and (6) the relief to the kidneys by allowing the bile to escape freely is also of importance, as they are thus enabled to perform their function more freely in relieving the system of septic and other materials." In the paper referred to M. Terrier relates several cases with the utmost detail, especially interesting on account of the bacteriological examination of the discharge from the fistula at different dates, conclusively showing the gradual diminution in the virulence of the discharge after the drainage has been proceeding for some days, and pointing to the need of rather more prolonged drainage than some of us have been wont to employ—i.e., until a bacteriological examination of the discharge shows it to be sterile, or nearly so.

Ulceration.—Ulcers of the gall-bladder or bile-ducts vary greatly in number, size, and depth, and also in clinical importance. They may be quite superficial, being mere abrasions of the epithelial lining of the mucous membrane, then being as a rule numerous and widespread, or they may be single and deep, extending into or through the muscular and serous coats. Between these extremes every variety may be found. Although cholelithiasis is the most frequent, typhoid fever and cancer are quite common causes. Cholera and tubercle are said to produce ulceration of the bile passages, but I have been unable to find any specimens in illustration. The slighter cases of erosion are seldom seen, though doubtless they frequently exist in cases operated on for gall-stones, and in others where the concretions are passed naturally, but the severer forms of ulceration are more frequently met with as the immediate cause of death. Ulceration is chiefly of importance on account of the serious sequelæ—stricture, perforation, fistula, peritonitis (local or general), hæmorrhage, septicæmia, and pyæmia. The inflammation accompanying ulceration usually extends to the peritoneal coat at the site of the ulcer and leads to a plastic peritonitis, which causes the adjoining organs to adhere to the inflamed surface; thus in the greater number of cases keeping the peritonitis local. Some years ago I pointed out that in nearly every case of gall-stones there are adhesions of the gall-bladder or ducts to neighbouring organs showing that peritonitis is a frequent or nearly constant accompaniment of cholelithiasis. It is doubtless a salutary phenomenon, as otherwise general peritonitis would be much more common, especially in the many cases where the adhesions permit of fistulæ quietly

[22] Netter and Martin, Archives de Physiologie, vol. ix., 1886.

Hosted by Google

forming between the contiguous viscera and where localised abscesses form without general peritonitis. The adhesions may, either by the anchoring of normally mobile organs or by subsequent contraction, themselves become sources of inconvenience or danger; as in the case of a woman, aged thirty-four years, under my care, who, besides suffering from severe spasmodic pain due to chronic catarrhal cholecystitis, had dilatation of the stomach owing to kinking of the pylorus caused by adhesions passing between it and the gall-bladder. After separation of the adhesions and drainage of the gall-bladder complete recovery ensued. The peritonitis may, however, become general, either from perforation or by extension to the peritoneum through the non-perforated walls. Under such circumstances prompt surgical treatment will be required or death will speedily follow. With regard to hæmorrhage, as the ulcer extends the vessels usually become thrombosed, but occasionally severe hæmorrhage results, leading either to hæmatemesis or melæna. The notes of the following fatal case were furnished me by my friend Dr. Peter McGregor of Huddersfield. "A temperate man, aged forty-eight years, had suffered from gall-stone attacks since the age of twenty-six years, but for a year had had no seizure and had gained two stones in weight. Without pain or other localising sign he began to vomit blood, and continued to do so two or three times a day until his death, which resulted from exhaustion in the third week. A necropsy revealed contraction of the liver with numerous gall-stones in the gall-bladder. One, the size of a large filbert, had ulcerated through the walls of the gall-bladder and was projecting into the peritoneal cavity. There was no peritonitis, and death was due to hæmorrhage from the margin of the ulcerated opening." It is to be borne in mind that hæmorrhage is predisposed to in these cases by the aplastic condition of blood occurring in long-standing jaundice. As ulceration is always associated with the presence of pyogenic organisms, septic absorption frequently occurs, leading to constitutional disturbances in the shape of septicæmia and pyæmia. Although cancer may lead to ulceration it seems probable that long-standing ulceration of the gall-bladder or bile-ducts may predispose to malignant disease as they are so frequently associated.

Stricture.—Stricture of the bile-ducts is one of the rarer sequelæ of ulceration, by which it is probably always preceded, except in those cases dependent on malignant disease, which I do not propose to consider under this heading. Though there is no reason why stricture should not be a sequence of typhoid ulceration, such has yet to be proved, and the only cases with which I am acquainted, or concerning which I can glean information, have followed on cholelithiasis or new growth. Stricture may only render itself evident after the original cause has passed away, as in three cases of stricture of the cystic duct and one of the common duct, where I myself removed the cause in the shape of gall-stones, and subsequently had to treat the strictures which afterwards developed, and in another case of stricture of the common duct, where the history of gall-stones was indubitable, though none were found when the abdomen was explored. With regard to the symptoms, stricture, if in the cystic duct, leads to a gradual enlargement of the gall-bladder, which may be quite painless or which may give rise to considerable distress; if in the common duct jaundice supervenes, at first being only slight, but ultimately becoming severe, and being associated with all the usual distressing and dangerous symptoms of chronic icterus. The liver enlarges and may descend to the level of the umbilicus; the gall-bladder may also enlarge, though if gall-stones have been the cause the gall-bladder may have become contracted and so be incapable of distension. Stricture of the hepatic duct is probably extremely rare, for I can only find an account of one case. Needless to say, stricture of the bile passages will scarcely call for diagnosis apart from its cause, though different treatment will be demanded when the disease is recognised at the time of operation. In stricture of the cystic duct the gall-bladder should be removed, as either a recurrence of the symptoms will occur when the wound closes or there will be a permanent mucous fistula. As an alternative the gall-bladder may be short circuited into the intestine. In stricture of the common duct cholecystenterostomy must be performed, otherwise a permanent biliary fistula will certainly follow; at times, however, this may be impracticable, and in such cases drainage alone may be feasible.

Perforation of the gall-bladder and bile-duct.—Perforation of the gall-bladder or bile-ducts must always be serious on account of an escape of the visceral contents into the peritoneal cavity, the imminence of the danger, however, depending on two factors—first, the nature of the extravasated fluid, and, secondly, the time allowed to elapse before surgical relief is afforded. The presence of healthy bile in the peritoneum, as might occur from an injury such as a stab, a bullet wound, or a blow, in a healthy individual may be tolerated for some time without serious damage, as in a case recorded by Thiersch, who successfully removed over forty pints of bile from the abdominal cavity after the gall-bladder had been ruptured by a blow. The experiments of Schuppel and Bosbrom apparently prove that the peritoneum can absorb extravasated bile without serious trouble, and there have also been several cases reported, in which extravasated bile has been successfully evacuated, either by tapping or by incision and drainage. Such a fortunate result cannot, however, always be looked for, as is shown by the specimens in some of the museums. In all the cases where the history is appended the fact of the long survival after so serious an accident is at once borne home, and the lesson is manifest that operations would in each case have given good hopes of success.

Rupture of bile duct due to injury.—Mr. Battle has reported the case of a boy who had been run over by a cab. At first there were no definite signs of visceral injury; by the seventh day, however, he was deeply jaundiced, with symptoms of acute peritonitis. Abdominal section was done on the eighth day, and a large quantity of almost pure bile evacuated, but no injury to the bile apparatus could be detected. He died on the ninth day, and post mortem the liver and gall-bladder were found intact, but the common gall-bladder was found completely torn through. This is apparently the first recorded case of such an accident, but I found in Guy's Hospital museum a specimen from a case of Mr. Bryant's, where there is a laceration of the hepatic duct near its origin, in which death occurred from peritonitis after a week's illness, two pints of bile-stained fluid mixed with blood clots being found in the peritoneal cavity. Gunshot wounds of the gall-bladder are rare. Courvoisier has mentioned six cases, in two of which the patients died within a few hours, in a third in six weeks from pyæmia, and in a fourth from septicæmia. The case related by Hans Kehr is, therefore, of considerable interest, as immediate laparotomy with suture of a bullet wound in the gall-bladder of a man aged thirty years was followed by recovery. It is of far more serious moment when the extravasated bile is diseased, as it for the most part is where there is distension of the gall bladder or any disease of the bile ducts; for in such cases the bile is infective and rapidly sets up a diffuse peritonitis, which, unless speedily operated upon, ends fatally. Even in such cases if the diagnosis be made at once and early operation done the prognosis is good, as in the case of a patient, aged forty-five years, who had suffered from gall-stone seizures for twenty-nine years, and whom I saw with my friend and colleague, Dr. Braithwaite. After symptoms of inflammation in the hepatic region extending over several weeks he suddenly became worse and showed signs of general peritonitis. I opened the abdomen in the right linea semilunaris, several pints of bile and pus being evacuated. The abdomen was washed out and drainage-tubes were passed between the liver and diaphragm into the right kidney pouch, and downwards towards the pelvis, with the result that the patient recovered and is now in perfect health. One of the most remarkable cases of perforation of the gall-bladder following typhoid ulceration successfully treated by abdominal section is reported by Dr. Monier Williams and Mr. Marmaduke Sheild in THE LANCET of March 2nd, 1895. The case occurred in a married woman, aged thirty-one years, who was operated on on the fifty-first day of the disease, when the gall-bladder was found to be rigid, thickened, and of a dark plum colour, with a sharply circular ulcer the size of a threepenny-piece near its neck, the gall-bladder containing about one and a half ounces of thick offensive pus; the abdomen was washed out; the distended intestines were emptied by puncture, and gauze packing with drainage adopted, the result being a complete cure. In cases of rupture of the gall-bladder from sudden pressure induced by straining at stool, by vomiting, sneezing, efforts in parturition, and even by blows over the hepatic region, there is in all probability in the greater number of such cases a predisposition to rupture in the shape of

Hosted by Google

thinning by ulceration or by long-continued distension; otherwise the accident would be much more common. Such cases show conclusively to my mind that it is folly to permit patients with distended gall-bladders, even though symptoms be only occasionally present, to go unoperated on. I know of several such cases where patients are living in a "fool's paradise" owing to such unsound advice. A careful operation in these cases is almost devoid of risk, but rupture is hazardous in the extreme. Massage in cases of distended gall-bladder I look on as the height of folly, though it has been advised by those who should know better. Attempts to force impacted calculi onward by pressure are well calculated to rupture the thinned wall of the gall-bladder or bile-ducts or to cause perforation through the base of an ulcer, leading to extravasation of germ-containing fluid into the general peritoneal cavity and probably to fatal peritonitis. In some cases the primary perforation may lead to the formation of a second cavity bounded by plastic lymph, which may again rupture and lead to a fatal peritonitis. The perforation of the gall-bladder may occur into adjoining parenchymatous organs, and on several occasions I have removed numbers of gall-stones from cavities in the liver produced by ulceration and perforation of the gall-bladder or bile-ducts and direct passage of the contents into the liver tissue. In such cases there are the usual signs of liver abscess following on the ordinary symptoms of gall-stones, which may have been present for years. If the ulceration and perforation occur from the common duct into the substance of the pancreas, acute pancreatitis may follow. If the ulceration advances towards the adjoining hollow viscera—stomach, duodenum, or colon—adhesions as a rule form and the perforation is effected quietly. In one case of this kind which I saw with Dr. Stewart, after a history of cholelithiasis followed by severe stomach symptoms, the gall-stones were vomited and complete recovery followed. In several cases I have seen large gall-stones ulcerate their way quietly into the intestine, only producing serious symptoms from mechanical intestinal obstruction. Rarely gall-stones have perforated into the pelvis of the right kidney, producing symptoms of renal calculus. Not infrequently the perforation may occur after adhesion to the parietal peritoneum, when the events described under simple empyema of a superficial abscess discharging gall-stones may follow. The symptoms of perforation of the bile passages are those of perforative peritonitis from other causes, but there will usually have been premonitory symptoms pointing to the origin of the disease. A sudden pain beneath the right ribs, often followed by collapse and usually succeeded by vomiting, general distension of the abdomen, and a rapid pulse form the prominent features of the disease. If the extravasation is extensive there will be signs of free fluid in the peritoneal cavity. Jaundice, if not present before the accident, usually comes on from absorption of biliary pigment by the peritoneum, and if the bowels can be moved the motions will usually be clay-coloured. If the case be not operated on, death will probably ensue within a few days from toxæmia and paralysis of the bowels, though in some of the cases I have quoted life was prolonged into the second or third week. As to treatment, in these cases medical treatment is useless, and giving opium for the relief of pain so disguises the symptoms that a fatal sense of security is given for a time, and when the mistake is discovered it is too late to operate. As soon as it is clearly made out that perforation has occurred, or even if it be suspected that such is the case, the abdomen should be opened in the right semilunar line. If pus and bile be found they should be rapidly wiped away with gauze or wool sponges, and if the extravasation has gone beyond the local area of disease the abdomen should be flushed with hot boracic lotion. The patient may be too ill to bear a prolonged operation, and if so free drainage, as in the case I have related, will probably do all that is necessary. In draining it may be borne in mind that the right kidney pouch forms a distinct peritoneal pocket, and that a drainage tube applied through a stab opening in the right loin affords a free exit for extravasated fluids coming from the neighbourhood of the gall-bladder. If the whole peritoneal cavity has been soiled a puncture above the pubes large enough for a tube to be passed into Douglas's pouch may be an advantage. If the patient be in sufficiently good condition to permit a search for the rupture, and it can be found, it may be closed by fine silk or catgut sutures, but as a rule it will be wise to open and drain the gall-bladder at the same time. Should marked cholecystitis be found the question of cholecystectomy may be worth considering, but when the patient is in a critical condition it is a mistake to attempt too much; and as a rule cleansing and free drainage will be all that are necessary or advisable at the time, the removal of the cause being left until the patient is better able to bear a prolonged operation.

The Ingleby Lectures

ON

THE OPERATIVE TREATMENT OF CANCER OF THE BREAST.

Delivered at Mason College, Birmingham, on May 19th and 26th,

BY BENNETT MAY, F.R.C.S. ENG.,

JOINT PROFESSOR OF SURGERY IN MASON COLLEGE, BIRMINGHAM.

LECTURE II.[1]

Delivered on May 26th.

GENTLEMEN,—I shall now proceed to consider the results which have been obtained from this method of operating, adopting Volkmann's three years limit as the standard of a cure for comparison with former methods. This means that the patient shall have had a full period of three years or longer after operation without local or internal recurrrence. Experience shows that the prospect of permanent immunity is then considerable. At the same time I do not accept this—or, indeed, any other period—as at all absolute, owing to the way in which minute deposits may temporarily remain quiescent and latent. I have seen external recurrence after an interval of eleven years, and not infrequently a patient dies from the disease five, six, or more years after operation, though in these cases I think some sign might have been detected within the three years limit. However, in this limited and provisional sense, I accept it as a cure. Then a distinction is to be drawn between local external recurrence and internal metastatic deposit as evidence of completeness of operation. The efficiency of the operation is more correctly measured by freedom from local recurrence than internal deposit, as the former is evidence that the operative limits were reached and nothing further could have been done. Moreover, it is supposed that cases are taken without special selection so long as they are operable. I believe the following is an exposition of the best work which has been done in the treatment of cancer of the breast on the lines of the radical operation described. The following table shows the recently published returns of three operators:—

TABLE A.—*Cases operated on by the Radical Method and observed for at least three years.*

Surgeon.	No. of cases.	No local recurrence.		Local recurrence.	Percentage of cures.	Date.
		Cured.	Died.			
Rotter	10	6	2	2	60·0	1896
Helferich	35	10	11	14	30·5	1896
Watson Cheyne ...	21	12	4	5	57·0	1896
Total	66	28	17	21	42·1	—

Percentage of cures (average) 42·1; percentage with no local recurrence 68; operative mortality 0.

Von Bergmann does a bold operation on ordinary lines, removing the breast widely with the paramammary tissues, systematically clearing the axilla, and in some cases removes the sternal portion of the pectoralis major. His latest statistics, however, do not come down later than 1885, when he was less careful about clearing the fascia, &c., than now, and I have not included them in this table. Rotter (Berlin) does a wide operation. He removes the whole of the pectoralis major and the pectoralis minor. He also removes the

[1] Lecture I. appeared in THE LANCET, May 22nd, 1897.

Hosted by Google

clavicular part of the major when the infra-clavicular glands are enlarged. In some cases he removes the supra-clavicular glands, but does not resect the clavicle. Helferich (Griefswald) does a similar operation, but without removing the pectoralis minor. Watson Cheyne does a wide, clean operation on ordinary lines, occasionally removing the sternal portion of the pectoralis major. He does not ordinarily remove the supra-clavicular glands. His results seem to be the best recorded, viz., 21 cases with 12 cures—57 per cent.

TABLE B.—*Statistics showing Gradual Improvement in Results.*

Operator.	Date.	Percentage of cures.
Billroth	1876	4·7
Esmarch	1876	11·8
Volkmann	1880	17·8
Kuster	1885	21·0
Konig	1885	23·0
Von Bergmann	1885	32·0
Average of Rotter, Helferich, and Watson Cheyne	1896	42·5

Looking to my own results I have seen that the effect of thorough removal is very marked indeed. I find it almost impossible to present these in a complete tabular form principally owing to the difficulty of tracing the hospital patients. I commenced to clear out the axilla as an addition to the ordinary operation in selected cases about 1887. These earlier ones, though not available in statisticial form, were of great value to me, and were largely instrumental in forming my opinion. Thus a woman whose breast and axilla I cleared in May, 1888, for a small scirrhous tumour, microscopically verified, is now alive and perfectly well. Another, operated on in April, 1889, in the same way is perfectly well to-day.

From the commencement of 1891 I have cleared out the axilla in every case of cancer that I have operated on with one exception, viz., a very feeble old lady, aged seventy years, with a small hard scirrhous nodule who presented anæsthetic difficulties. This has been the only exception. Since that date I have performed the complete operation more or less perfectly on seventy-eight patients, forty-four in private practice, and thirty-four in hospital. The ages ranged from twenty-eight to seventy-five years. There was not one death from operation, nor one even seriously ill so as to give anxiety. It is right to say that I have had one death from breast excision for a simple tumour, due to acute septic infiltration in hospital. I have found it impossible to trace the subsequent histories of a sufficient number of the hospital cases dated three years back to make them of any value for statistical purposes so they must be put aside altogether. Of the forty-four private cases I have a report up to date in every one. These cases are divisible into two periods, the first prior to May, 1894, and the second subsequent to that date. Those in the first group only are available for the three years limit, and they are 20 in number. Of these 7 are now alive and free from any sign of the disease, 11 have died from it, and 2 are alive, but show signs. Of the 13 in whom the disease has re-appeared it was solely internal in 7. I should state that this epoch contained an unusual proportion of bad cases, of complete failures and very early recurrences. I have no doubt the 24 in the second epoch will show much better results. In the first place I have continuously improved upon my method of operating, particularly in respect of wider removal of muscle and paramammary tissue. Then the selection of cases was more careful and judicious. Thus of 9 operations (private) in 1896 only 1 shows any sign of re-appearance, of 7 in 1895, 1 died within eight months, and 1 shows signs of internal deposit. All the others are quite well.

The advantages which have followed thorough and systematic operations are, I think, sufficiently apparent, and have fully established their superiority over the older methods. An important dissentient is to be noted in Mr. Frederick Treves, who considers that practically the results are no better than by the older methods while being more tedious and dangerous, but as he allows an average mortality of 5 per cent. for these older ones, and an average re-appearance within twenty months, it is clear that he does not do justice to the possibilities of the newer method while he considerably exaggerates its dangers and drawbacks, its average mortality being below 5 per cent., and immunity from return far more than twenty months.

I think it is more difficult to decide upon the merits of some of the more extensive operations which have recently been introduced, especially by our Transatlantic brethren. Halstead and Meyer do not consider the operation complete unless it includes also the whole of both pectoral muscles, every trace of fatty and connective tissue in the axilla and sub-pectoral region, and the supra-clavicular glands in the posterior triangle of the neck. Halstead's operation is rather startling in its extent and magnitude. The technique is not quite easy to understand, but it is fully explained in his article in the "Annals of Surgery,"[2] and also described by Jacobson in the last edition of his admirable work on "Operative Surgery." Suffice it to say that Halstead encircles the breast by a very wide incision which is carried below the clavicle on to the arm. A flap of skin is reflected down from the axilla and chest-wall, and is subsequently slid up to form a lining for the fornix of the axilla. Another incision bisecting the main one is carried over the clavicle to the neck and the flaps of skin are reflected. Both pectoral muscles are detached from the ribs and clavicle and the humerus and the cleaning of the axillary contents is commenced and carried from above downwards. The whole of the tissues are dissected away with scrupulous care, not a trace being left behind, and the whole mass is removed in one piece so that cancerous tissue is never cut into. He now also adds to this a dissection of the supra-clavicular glands from the posterior triangle of the neck. It is described as a bloodless operation, as many as 100 or more ligatures being required, and the time occupied is said to be three or four hours. He claims for it but little shock, as he allows no loss of blood, and as he has done it fifty-one times without a death he is entitled to do this. Halstead distinguishes between local and regionary recurrence. By the former he means return of the disease in the field of operation, in the scar, or in the glands above the clavicle. By regionary recurrence he means skin metastasis at a distance from the scar, and which he believes appear as independent formation being against the lymph current. The distinction, however, cannot well be maintained and seems superfluous. Of his 51 operations Halstead claims that there has been true local recurrence only in 3, but 8 have shown regionary recurrence, or 11 in all. In 5 the result was not known. The remainder, 34 in number, showed no external recurrence. Of these 10 had died presumably from internal metastasis, so that 24 or 50 per cent. may be considered as cured. The weak point in these statistics is that they are not based upon the three years or any limit—in fact, it does not appear that the three years' limit has been passed in more than three or four of them, a large number being within a few months of the publication. In any case they do not show better results than by the ordinary complete operation such as Watson Cheyne's. It is clear that in both cases the majority that die do so from internal metastasis without local recurrence. The operation seems to be one which may well be reserved for advanced cases where the muscles are infiltrated and the infra-scapular and cervical glands are enlarged, if, indeed, it is thought advisable to touch such cases at all. I believe it was not Halstead's intention to publish any more results till the three years had passed, so that a further and more valuable record should shortly be due.

Meyer's operation goes even further. He makes the usual oval incisions on a wide scale and bisects the upper by a vertical one carried up over the clavicle to the neck. The integumental flaps are dissected well back. Both the pectoral muscles are then removed entire, commencing at the humeral attachment of the major and throwing both inwards. These with all the infra-clavicular and axillary fat and lymphatics are carefully cleaned away with the knife absolutely and continuously working round the seat of disease, and never trespassing even on the belly of the muscle. The supra-clavicular glands are also dissected out of the posterior triangle of the neck through the vertical incision. Any defect of skin is made up by grafting in eight or ten days. This operation, he claims, adds only twenty minutes to the ordinary one, and the disability afterwards is not great. At the time of publication he appears to have done it only in one case, a few months previously, so that no

[2] Annals of Surgery, vol. xx., 1894.

Hosted by Google

opinion can be formed of its special merits. Further than this it is scarcely possible to go without amputating the entire upper extremity with the shoulder girdle. I believe this has been done a few times, though with indifferent success. It is clearly inadmissable, and can only be condemned as a dangerous and useless mutilation without corresponding advantage. Then at least one operator has removed the sternal glands from within the chest, a procedure which is not likely to be frequently followed. Heidenhain also includes the periosteum in stripping the muscles from their bony attachments.

There is diversity of view as to the treatment of the supra-clavicular glands. This is certainly our weakest point, and the most common seat of external recurrence, just as the axilla used to be. My own opinion is that if enlarged glands can be felt above the clavicle there is no hope of cure and the case is not suitable for operation. It is to be noted that these supra-clavicular growths often appear to grow very slowly, and that owing to the roomy space and fat in which they lie a long time may elapse before they show any sign of enlarging. Consequently by the time this has taken place the chain of glands beyond them, which is close to the lymphatic duct and passes into the chest, will be extensively infected, and the disease will have passed into a region where it cannot be followed. How far it should be carried as an addition to the ordinary operation is as yet somewhat doubtful. To clear out the posterior triangle of the neck means a considerable addition to the operation and is frequently unnecessary. If, however, it is found during the operation that the highest axillary glands are infected it is clearly necessary to follow them into the neck, unless the case is to be forthwith abandoned as hopeless. There is then a reasonable prospect of getting beyond the limits of the disease. It is not considered that divison or resection of the clavicle materially helps the exposure and removal.

I think it is very doubtful whether some of these more extensive operative procedures confer any additional immunity from recurrence at all commensurate with their severity. It is clear that in both classes of operation the majority of the fatal cases die from the internal metastasis without external recurrence, and against internal metatasis no operation can protect. It is very certain that but little good can result from these extensive measures if there exists some deep-seated nidus of infection which is beyond the reach of the knife. That such a source of infection exists is in many cases only too certain, though not apparent. Herbert Snow finds it in the bone marrow. He claims that this is the great obstacle to radical cure in breast cancer. This infection, he states, takes place in all ordinary cases within six months of the inception of the disease. The typical indication is a prominence of the sternum, though there may not be any more visible evidence for many years, the disease remaining quiet and latent. There is considerable force in his views, though probably much too sweeping. I have on several occasions recognised this enlargement of the sternum as an unfavourable prognostic sign, indicating bone infection.

So far there is no conclusive evidence that any corresponding advantage accrues from some of the more recent developments of the operation, and I am of opinion that the utmost benefit of which it is capable may be conferred in a large majority of cases by the one I have described as the standard. The cases for which this will not suffice are probably unsuited for operation. At the same time, final judgment must be suspended till we receive further reports of these procedures.

The clinical varieties of cancer of the breast vary, as is well known, within wide limits, and appear to me to depend very much on the age, habit of body, and constitution of individual patients. At one extreme is the large, soft, rapidly growing and vascular tumour known as medullary cancer, which occurs in robust, healthy young women, and in stout women of more mature years. These cases are most unfavourable for operation and, except in their earliest stages, are quite unsuitable. They furnish a large proportion of the early recurrences and failures, as the disease sometimes re-appears before the healing of the wound and spreads with great rapidity. Of all the unfavourably modifying conditions I think rapidity of growth is the worst. The actual duration is by no means the only criterion of the stage of the disease. A large tumour of the tuberous forms, of slow growth and unattached, has a much more favourable prognosis than an infiltrating medullary one in its earliest stages. At the other extreme is the small chronic dry infiltration of shrivelled and aged women, though not confined to old women. Opinions differ as to the propriety of operating in atrophic cancer. In my own opinion, it is a question of the stage of the disease. In an early stage they are the most favourable of all and should certainly be removed. Later, when there is any notable skin infiltration or attachment to the muscles, the most radical operation is not only ineffectual, but harmful. It is not only that an early reappearance may be expected, but the type of the disease is thereby changed and the recurrent malady may run its course in as many months as it would have occupied years if undisturbed. I have known a case extend over thirteen years of fairly comfortable life. Atrophic cancer has a remarkable faculty of attaching itself to surrounding parts, and of reproducing fibroid indurations in its recurrences, both regionary and metastatic.

On Paget's disease.—I have had four cases of this peculiar cancerous dermatitis of the nipple. I should advise immediate operation in every case of chronic eczema or ulcer of the nipple, even though no tumour is perceptible, as the relationship between this and cancer is constant. In all my cases the ulceration preceded the tumour by several years. In two of them the tumour was limited to the nipple, and of the kind known as duct cancer, and preceded by a bloody discharge from the nipple—a symptom of very grave significance.

On secondary operation.—Secondary operations are advisable only when the growths are small, solitary, and freely movable. I think these operable cases generally imply an imperfect primary operation, and should get rarer as we make this more efficient. In two of my cases only have I thought it advisable to remove recurrent nodules by secondary operation, and in neither was the result very satisfactory, as general infiltration soon showed itself. I have seen but one case, and that in the practice of a predecessor, which was greatly benefited by repeated operations, two small nodules being removed from the scar at intervals of four and three years respectively.

On the complete operation.—All cases should be subjected to the complete operation even in their earliest stages. Except as a palliative in a few rare cases and for benign tumours the incomplete operation—that is, of the breast alone—should be abandoned. The additional risk to life is scarcely appreciable, and the advantage of clearing the axilla, the next resting place of the disease, is obvious. After incomplete operations re-appearance takes place in at least 80 per cent. within six months. Even as a palliative the complete operation is much more effective, in particular in preventing that very distressing feature, œdema of the upper extremity. It is occasionally necessary to perform a palliative operation on a patient past hope of cure for the sake of the moral effect. To some women the verdict "too late" comes as a crushing blow, and it is more humane to yield to their request if this can be done with any prospect of relief. For instance, we may get rid of a foul and bleeding ulcer while the patient's spirits are maintained by hopefulness.

On the limits of the operation for cure and non-operable cases.—A judicious and careful selection of cases should be exercised and involves consideration of the constitutional state of the patient as well as the local conditions. Among non-operable cases I class: (1) large medullary cancers; (2) scattered tubercles in the skin and œdema; (3) internal metastasis of all kinds; and (4) œdema and solid enlargement of the upper limb. This I regard as an emphatic "Noli me tangere" and contra-indication. This waxy œdema is one of the most distressing features of the disease. I am sorry to say I know no means of relieving it. I have tried puncture, but it is worthless. Amputation at the shoulder girdle has been practised on a few occasions, and I have been asked by patients to do this; but even this heroic remedy does not arrest the progress. Among debatable cases I include:—1. Enlargement of supra-clavicular glands. I have hitherto regarded this as an absolute contra-indication, but I am inclined now to extend the field of operation to some of these cases. I would limit it, however, to small and movable tumours or to the condition I previously indicated of the highest axillary gland being found infected. Fixed and painful enlargements, with œdema of the limb, should not be touched. Before long we may expect some further evidence of the merit of this addition to the operation, as it is being extensively practised by some surgeons. 2. Cancer in both breasts. The appearance of the disease in the other breast is now commonly regarded as a late general infection

Hosted by Google

and not as an independent growth. It is explained by the free anastomosis and intersection between the lymphatics of the two breasts. It is rarely desirable to operate, but Jacobson records a satisfactory case. The surgeon must consider the probabilities in each case with the interval that has elapsed and the conditions of the re-appearance. It happened in two of my patients. In one of them I operated on the second breast with unsatisfactory results. In the other I did not operate on the second breast; the disease reappeared in this case two years after removal of the first, and, very curiously, it was preceded by enlargement of the axillary glands on the corresponding side.

Diagnosis.—The importance of early operation, obvious as it is, cannot be too strongly enforced. It is unfortunate that the disease is frequently so insidious in its onset that considerable advance has been made before the patient is aware of its existence. Another great hindrance to early operation is the difficulty of diagnosis in the incipient stages. The first care should be to place the patient in favourable circumstances for the examination. The chest should be quite undressed, so as to admit of easy examination of the pectoral region and axilla as well as of both breasts. In a matter of this urgency and importance accuracy of diagnosis should be subsidiary to promptitude in treatment, as there are cases in which it is impossible to be accurate without exploratory incision. The two conditions which give the greatest trouble are chronic inflammatory hyperplasia, and the case of a tense cyst situated deeply in the breast. The latter is distinguished by its mobility, globular outline, and verified by the exploring needle, which should never be overlooked as an aid to diagnosis. Chronic mastitis is often much more difficult to discriminate, and some experience in handling and exploring these indurations is needed. Students are taught to recognise cancer by the well-known evidences in a developed stage, when the malignant characters are patent to observation; and we are all more or less under the influence of these teachings. In the simple disease which often follows lactation or weaning the thickening is sensitive to the touch, firm, and elastic, but the outlines are more diffused than in cancer. On pressing the mass against the chest wall the induration and sense of tumour disappear. Then, again, the area of breast occupied is more diffuse and larger, or both breasts may be similarly affected. The same sort of dimpling of the skin may occur as in cancer, but this is quickly followed by fluctuation and suppuration.

It is prudent to come to a decision at the first interview—that is to say, if the surgeon is unable to convince himself of the non-malignant nature of the neoplasm it is better to take action at once. I deprecate the practice of keeping cases under prolonged observation to see how they will develop. Patients either get restive and will not consent to remain long in doubt, or, what is more common, if told to report themselves in a month they turn up in six months, when the mischief is done. Moreover, the sequel in about five cases out of six shows the delay to have been unwise.

A very important question arises as to the existence of any direct etiological relationship between chronic mastitis and cancer. It is generally assumed that such a relationship exists, that chronic hyperphasia is likely to become cancer, but the stages of development from this supposed pre-cancerous state have not been traced. There seems distinct clinical proof that cancer may be grafted on to it if prolonged. I believe this did take place in the case of one of my patients. This woman, aged forty-eight years, had chronic mastitis, and after an interval of three and a half years from its first incidence a small scirrhous nodule appeared on the site. This made me regret being too precise and nice in my diagnosis. There can be no doubt that before proceeding to do one of these wide operations we must first positively satisfy ourselves that the disease is malignant. In a large proportion—too many, indeed—this is only too obvious. In doubtful cases a preliminary exploratory incision is to be made, and precaution is to be taken against auto-infection. The knife should be changed and the hands of the operator as well as the surface of the breast washed and the incision plugged with sterile gauze. Can we rely upon the naked eye appearance of the cut surface? I think so. The fresh cut section of cancer is unmistakeable, quite different from the leathery toughness of chronic mammitis. Some contend that the surgeon, if not an experienced pathologist himself, should always be accompanied by one with his freezing microtome. This, however, is a luxury which cannot always be had, unless he is to be an official provided at State expense, as suggested in America. One is very glad of the opinion of a skilled pathologist, but in case of a conflict of opinion the responsibility of deciding and acting would remain with the operator.

In closing, let me summarise by saying that so far as is at present known our only hope of advancement lies in the direction of more thorough and more early operation. The limit of what is possible in the former direction will soon be, if it is not already, reached. The result must carry conviction that we may hopefully anticipate a real cure in at least 30 or 40 per cent. or, some would say, 50 per cent. of our cases. I would not like to place 30 per cent. as a limit, but it is with somewhat chastened hope that I look for anything beyond. Longer observation is required, particularly as to the future development of those cases which pass the three years limit. Even now, however, the operation in too many cases is not practised to the best advantage and is not used for all it is worth. Certainly some of the disrepute and prejudice which have surrounded it may fairly be ascribed to the incomplete and inadequate manner in which it is too often done by men who have had no proper surgical training, and whose ill results serve to injure the cause as a whole, and to reflect prejudicially on the work of others. The fact is it has been everyone's operation because it is thought to be easy, but now that surgery is specialised to such an extent these easy happy-go-lucky methods should be abolished in this as in other branches of surgery.

In respect to the second point—more early operation—much has yet to be accomplished. I think, however, that I observe some improvement in this direction and that we now operate at a somewhat earlier average stage than was customary fifteen or twenty years ago. I gladly testify to the alertness of the profession in this respect. When undue delay occurs it is usually the fault of the patient who has concealed it from herself, her friends, and her medical attendant till too late. For this the well known want of success of the operation is partly responsible. If we can show better results women will probably be less reluctant to undergo treatment. I think in lay circles as well as medical there is an increasing recognition of the value of early and complete operation as offering the only hope of cure. For the present all pretensions to influence the course of the disease by other measures seem to have subsided, and one after another the worthless cancer cures have ceased to distract the public mind.

In thanking you for your kind attention I am too well aware that I have added nothing of novelty or weight to what has already been better said by others, but I hope some service may have been done by showing that the operation deserves more careful study and attention than it commonly receives. British surgery has been rather lax in its treatment of breast cancer, and in particular in our own district I think we have much leeway to make up.

TYPHOID SERUM REACTION.

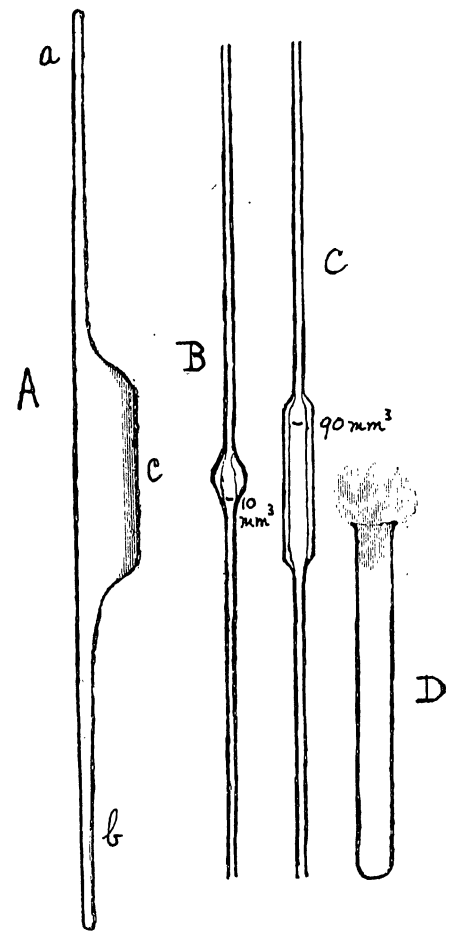
BY W. C. C. PAKES, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.,
ASSISTANT DEMONSTRATOR OF BACTERIOLOGY AT GUY'S HOSPITAL.

(From the Laboratory at Guy's Hospital.)

ALTHOUGH the typhoid serum reaction has been very generally viewed with favour by most observers as a test for enteric fever, some do not consider it to be of such value. There seems to be a tendency on the part of nearly all to admit that the reaction must be accepted with certain reservations, particularly when a negative result is obtained. It was in order to study the conditions which may be responsible for the different and somewhat anomalous results that I began a series of observations, during the course of which I have examined the sera of sixty different subjects. A brief *résumé* of the methods and conclusions of some of the different observers will help to explain why I adopted a particular technique.

Grünbaum,[1] who appears to have been the first to study

[1] THE LANCET, Sept. 19th and Dec. 19th, 1896.



Hosted by Google

the question systematically, uses serum which he dilutes with broth in strengths varying from 1 in 4 to 1 in 32. He considers that the test is of value when a positive reaction is obtained within a definite time; he adopts the half-hour time limit which was suggested by Gruber and Durham. Durham,[2] who uses a similar technique, failed to get a reaction in three undoubted cases of enterica as late as the sixteenth day of illness. He looks upon the reaction with favour if a positive result is obtained, but does not consider a negative result to be of much value. Widal[3] dilutes the serum with nine times (approximately) the amount of an actual broth culture of the bacillus, and makes observations as long as twenty-four hours after the mixing. He—with Catrin, Chantemesse, and Sicard, who adopt his methods—views the test with great favour, although he has found that a 50 per cent. serum from a normal person may give a positive reaction. Wyatt Johnston and MacTaggart,[4] who use dried blood subsequently diluted with water, constantly use the reaction as a test for enteric fever. Block,[5] Biggs, and Park[6] use diluted serum and, with certain reservations, think the test is of value. Von Jez,[7] who uses twenty drops of serum in 10 c.c. of broth and makes observations during as long a period as twenty-four hours, maintains that the reaction is not characteristic of enteric serum and has no specificity, The differences in the results obtained by these observers appear to bear some relation to the differences in technique, and until some generally accepted dilution and "reaction time" are adopted, different results will continue to be obtained.

Regarding the dilution, Widal and others dilute the serum with the actual broth cultivation of the bacillus typhi abdominalis. There is the objection to this method that the first portions of the serum which come into contact with the bacilli may be as strong as from 80 per cent. to 50 per cent. As, therefore, the serum of some normal people will give a decided and quick reaction, possible fallacies may occur. Wyatt-Johnston, moistening the dried blood with water, is quite unable to determine the amount of the dilution. He uses a small dilution and speaks of "partial reaction." Although this method has been attended with consistent results in his hands, other observers have not obtained such good results. Biggs and Park raise another objection to the method—viz., the formation of what they term a "pseudo-reaction." Consistent results would hardly be expected from an observer like von Jez, who is content to "drop" the serum into a measured quantity of broth. The "reaction time," or interval during which the observations are continued, has been more variable even than the amount and method of dilution. Grünbaum limits the time to half an hour, whilst Widal, von Jez, and others limit it only to twenty-four hours.

Early in December, 1896, I began a series of observations upon this reaction. Having some of the results of previous observers before me, I decided to make a comparison of the effects of 5 per cent. and 50 per cent. serum upon the bacilli during the first half-hour and after twenty-four hours respectively. I also made observations regarding the delicacy of the reaction of 5 per cent. serum microscopically as compared with that of the same dilution macroscopically. The five columns of reactions in the table are therefore as follows:—Column I., 5 per cent. serum microscopically within half an hour; Column II., 5 per cent. serum microscopically at the end of twenty-four hours; Column III., 5 per cent. serum macroscopically at varying periods; Column IV., 50 per cent. serum microscopically within half an hour; and Column V., 50 per cent. serum microscopically at the end of twenty-four hours. The serum was taken from three classes of subjects: (1) those who were suffering from, or who had suffered from, enteric fever; (2) those suffering or convalescent from other diseases; and (3) normal people. I have taken every precaution I could to satisfy myself that all those in classes 2 and 3 had never suffered from any disease resembling enteric fever during their lives. All the normal people, and those who had enterica several years ago, were either medical men, members of their families, or nurses.

Collection of the blood.—Fig. A of the diagram represents the pipette I have used throughout, with the blood-clot (darkly shaded) in the barrel, and the serum (lightly shaded) collected in the lower end. The shape is sufficiently indicated in the diagram. The diameter of the barrel—i.e., the tubing from which it is made—is about half an inch; the pipette ends are fine, but not of capillary dimensions, and are not sealed before use; the total length is five inches. Several are made at one time, put into seven inch test-tubes and sterilised in the usual manner. The lobe of the ear is cleaned with lysol, or other antiseptic; this is washed off with alcohol which is allowed to evaporate. The lobe is pricked with a sharp hare-lip pin or bayonet-pointed needle, and the ear gently squeezed. As the blood issues the end (*a*) of the pipette is held to the drop whilst the other end is depressed; the blood will now run down without any suction. When four or five drops, which is quite sufficient, have been collected the

mouth is applied to the end (*b*) of the pipette and very gentle suction exerted, the side (*a*) of the barrel being dependent. If the suction is gentle the blood will run into the barrel and will remain in a layer at the bottom without the formation of bubbles. If the suction is too great, or the diameter of the barrel too small, a bubble will probably form across the barrel, in which event the amount of available serum is diminished. The open ends are now quickly sealed and the pipette rested on a tumbler or other convenient stand, so that the part (*c*) is dependent. In this position it is allowed to remain until the blood is perfectly coagulated; from twenty minutes to half an hour is generally necessary. The pipette is then replaced in the test-tube and fixed in a vertical position. After a few hours the serum will be found free from corpuscles in the lower end.

I consider that the ear as a source of blood is in every way preferable to the finger. As much, if not more, blood can be abstracted without causing any pain. Several of my cases were small children and not one of them cried during the operation, although on a few occasions I had to squeeze the ear well, owing to the small size of the lobe. One of the chief advantages which Wyatt-Johnston claims

for his method is that no skill is required for the collection of the blood. As it might have been urged that my method required a certain amount of skill or previous experience, I gave my pipettes to several medical men who had never collected blood for examination, together with an account of the method of collection which I have detailed above, and in every case I have had the pipette returned to me with the blood collected excellently. I consider that the method is easier because the ends are cut off square, instead of having to be broken off with sterile forceps, as is the case when the ends are sealed.

Dilution of the serum.—In order to dilute the serum I have used two capillary pipettes, represented by B and C in the diagram (B is graduated at 10 mm.^{3} and C at 90 mm.^{3}), and a small test-tube three-eighths of an inch in diameter and two inches long, similar to those used by Durham.[8] The end (*b*) of the blood pipette is filed and broken off just above the level of the serum. The end of the pipette B is inserted into the open end, and 10 mm.^{3} of the serum are drawn up into it. (If the calibre of the pipette B is not sufficiently small to allow this, the bottom end of the serum-containing tube is broken off and the serum is allowed to run into the pipette by capillary attraction.) The 10 mm.^{3} of serum are now introduced into the test-tube D and 90 mm.^{3} of sterile broth or salt solution are added by means of the pipette C and well mixed with it. In order to make the 5 per cent. dilution a loopful of this diluted serum is placed on a coverslip and the same loopful of an eighteen-hour broth culture of the bacillus typhi abdominalis is mixed with it. The coverslip is inverted on a hanging-drop slide and at once examined. To make the 50 per cent. dilution a loopful of the broth culture is placed on a coverslip and a drop (of equal size) of the serum is placed near it by means of the pipette B. The two drops are then well mixed, inverted on the hanging-drop slide, and examined. For the macroscopic sedimentation test 90 mm.^{3} of the broth culture are added to the diluted serum in the test-tube. Until Wright[9] published the account of his technique I had followed Durham's method and allowed the sedimentation to take place in the test-tube, but since that publication I have sucked the prepared emulsion from the test-tube into a sedimentation-tube after Wright's pattern. The massing and sedimentation are certainly more easily seen than in the test-tube and after a shorter interval. Even after adopting Wright's method I have not found that human serum, however well it reacts microscopically, will give such quick reactions as Durham[10] describes with the sera of artificially immunised animals. Wright's method of diluting I do not consider so desirable as that by means of capillary pipettes in a test-tube.

A glance at the table on p. 1461 shows several interesting facts. Cases 1 to 20 were either suffering from enteric fever or had suffered from the disease within two years. Of these all gave a reaction with 5 per cent. serum in less than half an hour except Case 2. As will be seen, I made two examinations of this patient—the first six days after the onset of the disease and the second sixteen days after the onset. At the first examination I got no reaction within half an hour. I was unfortunately not able to examine the slides after twenty-four hours, but there was no sign of reaction after the lapse of four hours with either the 5 per cent. or 50 per cent. serum. There was, however, no sign of sedimentation in the test-tube after twenty-four hours. Eleven days later, when I made a further examination, I obtained a marked reaction with the 5 per cent. serum within half an hour, and a reaction with 50 per cent. serum in less than two minutes. There was also a macroscopic reaction in three hours. Cases 21 to 30 had suffered from enteric fever from three and a half to thirty years previously to the examination. Cases 21, 22, and 23 gave no reaction with 5 per cent. serum even after twenty-four hours, but each gave the reaction with 50 per cent. serum within half an hour. Cases 24 and 25, however, who had suffered from enteric fever six years before, gave a very marked reaction with 5 per cent. serum within the half hour. One of these two cases had one and the other two relapses. Of the remainder Cases 26 and 30 alone gave a reaction, and that with 50 per cent. serum only. Cases 30 to 60 had never suffered from enteric fever. Of these not a single one gave the reaction with 5 per cent. serum within half an hour; two gave a reaction after twenty-four hours. Eleven gave a reaction with 50 per cent. serum within half an hour, and three gave a reaction after twenty-four hours that did not show it within the half hour.

The results of my observations lead me to the following conclusions: 1. As a quantitative reaction (when the serum is sufficiently dilute and the "reaction time" short) the test is of great value when the result is positive. 2. If a sufficiently long interval has elapsed since the onset of the disease a negative result is of value. When a large number of observations have been made during the earlier periods of the disease, to determine the average time of the appearance of the reaction in the serum, the negative results will be of still greater value. 3. The microscopic reaction is more speedy and more delicate than the macroscopic reaction. 4. The results of von Jez and others who have used a technique similar to his only show that too strong a serum, acting for as long a time as twenty-four hours, may give a reaction when it is obtained from a normal subject. They bear out the statement of Grünbaum that the reaction must be considered as a quantitative, and not as a merely qualitative, one.

In conclusion, I must express my indebtedness to Dr. Goodall, Dr. Goodhart, Dr. L. E. Shaw, Dr. F. Taylor, and Dr. Washbourn for their kindness in allowing me to examine patients under their care and to Dr. Washbourn for much valuable assistance.

Since writing the above, I have read the account which Professor Delépine[11] gives of his technique. It will be seen that with the manner of collecting the blood in sterile pipettes I am in accord, and I think that he will agree with me that the method which I have described is not beyond the capacity of medical men, as Wyatt-Johnston maintains. With regard to the difficulty of making exact dilutions by means of graduated pipettes, "when eight or ten observations have to be made in a short time," I do not agree. On one occasion I made six observations in half an hour; each observation included making the 5 per cent. and 50 per cent. dilutions for the hanging-drop specimens and the addition of the 90 mm.^{3} of the broth culture to the dilute serum. With a good blow-pipe at hand thirty or forty of the pipettes I have described can be made in an hour, and graduated in another hour, by any capable laboratory assistant. Directly the pipettes have been used they are dropped into a cylinder containing 5 per cent. lysol, and subsequently cleaned and sterilised as required. Professor Delépine also objects to exact measurements by graduated pipettes, because it is not always easy to get a small drop of serum out of the blood. I do not think that he will find any difficulty in obtaining 20 mm.^{3} (one-third drop), which is all that I require.

A PLEA FOR THE LARGER USE OF ERGOT IN OBSTETRICS.[1]

BY THOMAS MORE MADDEN, M.D. TEXAS, F.R.C.S. EDIN., M.A.O. (*Honoris Causâ*) R.U.I.,
OBSTETRIC PHYSICIAN AND GYNÆCOLOGIST TO THE MATER MISERICORDIÆ HOSPITAL, DUBLIN; CONSULTANT AND EX-MASTER TO THE NATIONAL LYING-IN HOSPITAL, CONSULTING PHYSICIAN TO THE CHILDREN'S HOSPITAL, DUBLIN, ETC.

THE position of the practitioner who, after somewhat extended obstetric experience, finds himself returning to a question such as the use of ergot in obstetrics, in the discussion of which he has formerly more than once taken part, and which long before he had entered either the profession or the world was fully debated and apparently decided, may possibly serve to recall the task of Sisyphus as described by the poet:—

> "With useless endeavour,
> For ever, for ever,
> Is Sisyphus rolling
> His stone up the mountain."

Nevertheless, that it is not quite so superfluous to reconsider this subject at the present time as it might thus seem can, I think, be easily proved. In few respects are the changes

[11] Brit. Med. Jour., April 17th, 1897.
[1] A paper read before the Section of Obstetrics of the Royal Academy of Medicine in Ireland on April 23rd, 1897.

that have been effected in midwifery practice since my student days more marked than with regard to the views then and now generally adopted in reference to the employment of ergot. At that time this drug was very commonly resorted to, and often with little discrimination, in labour cases. A few years subsequently the reaction which was inevitable against that malpractice set in, and has continued to operate and increase up to this period, when, the pendulum of professional opinion having been swung back to the opposite extreme, comparative desuetude has replaced the former abuse of the most potent agent at our command in many cases of powerless labour and impending post-partum hæmorrhage. This result has, I think, been fostered by the teachings of some recent authorities, by whose writings[2] a trend of modern opinion distinctly adverse to the general employment of ergot during labour has become established.

In the following remarks I therefore propose to consider very briefly whether the radical change thus effected is altogether correct in theory and advantageous in practice or not. On the former point it may be observed that some of the objections now urged in obstetric text-books against the general use of ergot are apparently founded on the recent investigations of scientists, who, in the laboratory, have examined the chemical constituents of this drug and their action in the case of some of the lower animals, rather than on actual experience of their effects in the lying-in room. It should therefore be borne in mind that, as Mr. Squire has pointed out, "neither the chemistry of ergot nor the physiological actions of its constituents have yet been definitely determined," and that, moreover, no abstract dicta, however authoritative on these points, can outweigh the testimony to the contrary effect of the countless number of obstetric practitioners who have long used preparations, such as the fluid extract of ergot or Bonjean's ergotine (which are stated to contain a toxic agent of deadly potency in the case of the animals experimented on by Kubert), without any injurious results, when judiciously employed, in the cases of parturient women.

The dangers ascribed to the administration of ergot during labour by the writers referred to include, firstly, its possible fœticidical effects; secondly, the probability of giving rise to such irregular uterine action as may occasion subsequent retention of the placenta; and, thirdly, the direct toxic effect on the maternal system that has been attributed to this drug. With regard to the first of these objections, I need not here occupy any time, as it was disposed of long since by the observations of Dr. Denham, and more recently and conclusively by the experience of our distinguished President, Dr. Atthill, whose views on this subject have been too freshly impressed on us to need any recapitulation. As to the second and third of the reasons, which, as just mentioned, are assigned for the general non-employment of ergot during parturition, I know not how I can deal with them more readily than by a short reference to my own clinical notes. Having, however, employed ergot in a very large number of instances in hospital and private practice during the last twenty-six years, within which, for some time, I occupied the position of master of one lying-in hospital and assistant master of another, it would involve more labour and occupy more space than might now be desirable, were I to refer to the record of all the occasions on which I have administered this ecbolic. I shall therefore submit merely a brief statement of the circumstances under which, in a series of 150 cases, ergot or its preparations were resorted to in midwifery practice, together with the results of its exhibition in each instance.

Abstract of 150 obstetric cases in which ergot was used.—In 70 of these cases the patients were primiparæ; in 80 they were multiparæ. In 148 cases the maternal result was favourable; in 2 instances the cases terminated fatally—viz., in 1 from septicæmia and another from typhoid fever which had commenced before parturition. In 95 cases the drug was given before the birth of the child—viz., in 15 cases for delay from inertia in the first stage of labour, and in 80 cases for delay similarly occasioned in the second stage or for the prophylaxis of hæmorrhage or for other complications then. In 92 of these instances the children were delivered alive either by uterine action or by the forceps; in 3 they were stillborn; and in 2 of the latter cases, the child being then putrid, no toxic effect could be ascribed to the ecbolic. Of the 95 cases in which ergot was given before the birth of the child in 86 the placenta was normally expelled, and in 9 its removal had to be assisted or effected—viz., in 4 for morbid adhesions, in 4 for persistent uterine inertia, and in 1 for irregular or hour-glass contraction. In 55 cases ergot was given after the birth of the child—viz., in 25 during the third stage to hasten expulsion of the placenta or prevent hæmorrhage, and in 30 after completion of labour for the arrest of post-partum flooding or, for some other reasons, to stimulate and secure tonic contraction of the uterus.

My own experience, as just summarised, points to the conclusion that many of the evil effects that have been ascribed to ergot are the result of its abuse, and therefore afford no reason against its judicious employment. Thus, for instance, if ergot be given in unsuitable cases and at unsuitable periods of parturition or in those small, inefficient, and frequently repeated doses that are now advocated, the results that may follow should, I think, be accredited to the practitioner rather than to the agent he has so resorted to. At the same time, I need hardly disclaim any desire to minimise in the least the necessity for all due caution in the use of this potent drug, or the dangers to mother or child which may be consequent on its misuse, and which are too obvious to need any detailed reference here. I may, however, on the latter point at least repeat that, as I long since elsewhere observed, "under no circumstances should ergot or ergotine be given during labour until the os uteri is fully dilated or so dilatable as to allow of delivery by the forceps if the child be not expelled by uterine action within an hour of its administration or at any time sooner that this may become necessary, as otherwise the fœtal circulation might very probably become arrested by the protracted tonic or unremitting uterine action which is the characteristic effect of this drug." That effect was also brought under notice in a former paper of mine, in which I instanced the fact that in a series of cases that came within my cognisance in which ergot had been given too early before forceps delivery, in rather more than one-fourth of these instances the children were stillborn. And hence for my own part I would almost as soon entrust a case of instrumental delivery to a student just commencing his midwifery as allow him or the nurse to administer ergot until thoroughly conversant with the principles which should direct its employment and the evils that may result from its improper exhibition.

The conditions and circumstances under which ergot may be employed in obstetrics.—These may be here briefly stated, although, as will be seen, I ascribe a wider range of utility to ergot in midwifery practice than is generally conceded. Nevertheless, I would presume to observe that my views are the result of actual clinical experience which it may not be easy to disprove by any merely theoretical objections, however strongly expressed. Judging from the recent literature of this subject it apparently is not superfluous to premise that to use any preparation of ergot safely and effectively in the labour cases referred to it is essential, (1) that the presentation should be natural or cranial, except in some instances of breech presentation, in which it may possibly be necessary to deal at once with uterine inertia; (2) that there should be no marked disproportion between the fœtus and mother or any other physical impediment in the genital tract to delivery; (3) that the os uteri, if not previously fully dilated, should be so dilatable as to allow of speedy extraction by the forceps when necessary; and (4) that the preparation selected, the dose, and the method in which it is employed should be well calculated to produce the required effect.

Subject to the foregoing conditions, ergot may with utility be employed when actually indicated and judiciously administered either before, during, or after the second stage of labour. That is to say, it may be given before the full dilatation of a dilatable os—(1) in some instances of long delay from uterine inertia in which there is imminent danger to mother or child; or (2) risk of subsequent flooding from further protraction of the case. During the second stage it may be employed (3) in labour rendered abnormally tedious by deficiency of uterine action or otherwise complicated, and in which the presentation is natural and no other impediments to delivery exist; or (4) for the prophylaxis of apparently impending flooding. During the third stage ergot may be resorted to (5) for the expulsion of the placenta when retained by inertia; or (6) for the arrest of loss of blood. After delivery this ecbolic may be employed either immediately (7) to check or prevent hæmorrhage, or, subsequently (8), to produce tonic

or permanent contraction, and, by sealing up the uterine vessels, thus lessen the liability to bacteriological invasion or sepsis; or else at the same time it may be exhibited (9) for the purpose of expelling clots from the womb and so arresting after pains. Lastly (10), in the majority of multiparous patients ergot may be administered during the puerperal period with the object of stimulating the muscular tonicity of the uterus, accelerating the process by which its return to a normal condition after parturition is effected, and thus obviating the future possibility of chronic subinvolution.

Method of employing ergot in obstetric cases.—To produce the desired effects in the cases above referred to it is obviously necessary, as I may repeat, that ergot should be administered in the form, dose, and method best calculated to secure speedy and permanent contraction of the muscular tissues. Under no circumstances, therefore, should ergot be given in obstetric practice in those small, utterly inefficient, and frequently repeated doses that have been recommended by several modern authorities, but which, in my opinion, are calculated to do more harm than good by producing irregular and evanescent waves of muscular contractility instead of that firm, regular, and tonic uterine contraction by which alone persistent inertia may be overcome, the fœtus or the placenta expelled, post-partum hæmorrhage prevented or arrested, retained clots and membranous or placental débris dislodged, and subsequent sepsis or still later subinvolution may be obviated. With these objects in my early days an extemporaneous infusion of the crude, freshly powdered drug was most generally employed, and though troublesome to prepare and, nauseous to take, was of unquestionable ecbolic activity. This in turn was replaced by the no less efficacious liquor ergotæ of the British Pharmacopœia or by a glycerine solution, such as Long's, which, when I was assistant physician to the Rotunda Hospital, was as largely and usefully employed as any of the more recent preparations of ergot have since been. Amongst the later I may more especially mention Bonjean's ergotine, Oppenheimer's ergol, and Burroughs, Wellcome, and Co.'s tabloids of ergotin and of its citrate, each of which I have with advantage employed in many instances. At the same time, however, I may confess my possibly antiquated predilection for the fresh liquid extract of the Pharmacopœia, which I have found, when, as I think, properly administered—that is to say, in suitable cases and in doses of from two to three drachms by the mouth, together with the simultaneous exhibition of another drachm, or even two, by deep hypodermic injection in the gluteal region—generally most reliable as a safe and efficient ecbolic. To act thus, however, ergot—whatever preparation be selected—like all other potent drugs, must be judiciously employed, or, in other words, should be given only in suitable cases and conditions, at the proper time, in an effective manner, and with due precautions.

Dublin.

THE BACTERIOLOGICAL DIAGNOSIS OF TYPHOID FEVER.

BY GEORGE R. MURRAY, M.A., M.D. CANTAB., M.R.C.P. LOND.,

HEATH PROFESSOR OF COMPARATIVE PATHOLOGY IN THE UNIVERSITY OF DURHAM; PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

THE examination of sputum for tubercle bacilli and of the membrane from suspected cases of diphtheria by the preparation of cultures has in each case proved to be such a valuable aid to diagnosis that the wish has often been expressed that a similar bacteriological test for the presence of typhoid fever was available. We have now good reason to believe that such a want has been supplied by Widal's method, which bids fair to be of great assistance in determining the true nature of doubtful cases of typhoid fever at an early stage of the disease. As the new method is still on its trial I venture to record my own experience of it. The gradual development of the test and the various ways in which it may be applied have been so recently described by Professor Delépine[1] in this country that a short description only will be given of the method adopted in the cases which I have examined.

[1] THE LANCET, Dec. 5th, 1896, p. 1589; Brit. Med. Jour., April 17th, 1897.

It is well to recognise that this test can be rapidly made at the bedside, and in many cases a positive result can be thus obtained earlier than when a specimen of the blood has to be sent to a laboratory for examination. In order to apply the test in this manner it is necessary to be provided with a pure broth culture of the typhoid bacillus which has been grown for from eighteen to twenty-four hours in an incubator at 37° C., a microscope fitted with a lens having a magnification of from 200 to 300 diameters, or, still better, with a $\frac{1}{12}$th in. oil immersion lens, a platinum loop, a pair of forceps, a spirit lamp, slides and cover-glasses. These can be carried in a handbag, so that the test can be applied in a private house as well as in a hospital ward by anyone who has the requisite knowledge of bacteriological methods. Before carrying out the test a specimen of the broth culture must be examined under the microscope so as to make sure the bacilli in it are actively motile and show no agglomeration. Thirty-four cases have been examined. In twenty-two freshly-drawn blood, in eight dried blood, and in four serum has been used. The test has been applied in the manner recommended by Professor Delépine as follows. The lobule of the ear or the tip of a finger is pricked with a clean needle, and of the blood thus obtained one platinum loopful is placed on one corner of a clean cover-slip. Nine loopfuls of the broth culture of the typhoid bacillus are then put separately on the same cover-glass and uniformly mixed with the blood by means of the platinum loop. The cover-glass is at once turned over, placed on a glass slide, and examined under the microscope. By this method the reaction is rapidly developed.

Of fourteen cases of typhoid fever in which the reaction was obtained with fresh blood it was immediate in eight, well marked agglomeration of the bacilli being seen directly the specimen was put under the microscope. In the remaining six the agglomeration was quite distinct within fifteen minutes of the first examination of the specimen. When the reaction was not observed within a few minutes it was found to be advisable to run a little melted paraffin round the edge of the cover-glass so as to prevent evaporation from the edges of the specimen and so preserve it for more prolonged examination.

In twenty-four cases in which a clinical diagnosis of typhoid fever had been made at the time of the examination the reaction was obtained. Some of the cases were convalescent, but in none had the temperature been normal for more than three weeks. These cases are arranged in the following table:—

Table of Twenty-four Cases of Typhoid Fever in which Widal's Reaction was obtained.

Sex.	Age.	Date of examination from onset of illness.	Method of testing.	Result.
M.	11	5th day.	Dried blood.	Immediate reaction.

In one case there had been a typical severe attack of enteric fever, but the temperature had been normal for six weeks at the time the blood was examined, and no reaction was obtained, although the specimen was kept under observation for two hours. In another case which had been admitted to the hospital as a doubtful case of enteric fever of five days' duration the temperature became normal on the seventh day. The blood was examined on the twenty-seventh day, but no reaction was observed, so that the case cannot be considered as one of enteric fever at all.

From this it will be seen that in no case did the reaction fail to occur when the blood or serum was examined during the febrile stage or during the first three weeks of convalescence. The only case in which it was not obtained was that in which convalescence had already lasted for six weeks. In one case of acute pulmonary tuberculosis a very slight agglomeration of the bacilli was observed, but the patient was a Chilian who could not speak English and we were unable to ascertain whether he had suffered from typhoid fever previously or not. The blood of two normal persons gave no reaction, nor was any agglomeration of the bacilli observed in the following cases: ulcerative endocarditis with subsequent peritonitis and pleurisy due to a diplococcus, acute rheumatism followed by exophthalmic goitre, scarlet fever with middle-ear disease and meningitis, influenza with severe gastro-intestinal symptoms, and measles. In some of these cases the result of the test was of much assistance in excluding typhoid fever at an earlier date than was possible by the clinical symptoms alone.

In conclusion, I wish to express my best thanks to those who have so kindly allowed me to examine their cases, and especially to Dr. H. E. Armstrong, the medical superintendent of the Newcastle City Hospital for Infectious Diseases, and Dr. C. V. Dingle, the resident medical officer, for much valuable assistance.

Newcastle-on-Tyne.

A NOTE ON THE BACTERIOLOGICAL CONDITIONS PRESENT IN ULCERS TREATED BY OXYGEN GAS.

BY DAVID SEMPLE, M.D., M CH. R.U.I., D.P.H. CAMB.,
SURGEON-MAJOR, ARMY MEDICAL STAFF.

IN a very interesting paper read before the British Medical Association at Carlisle in July last,[1] Mr. George Stoker described in detail his method of the surgical uses of oxygen gas, and gave a series of cases of chronic ulcers and burns successfully treated by this method. In the same paper he also gave, in conjunction with Mr. George Dineen, a short bacteriological account of the cases so treated, and a summary of conclusions.

With a view to testing the accuracy of these conclusions, advantage was taken of the opportunity of making cultivations from a series of cases of chronic ulcers undergoing the oxygen treatment at the Royal Victoria Hospital, Netley. The methods pursued were in the main the same as described by Mr. Stoker in his paper—viz., cultivations were made from the ulcers before the application of oxygen and at intervals during the treatment. In all cases the cultivations were made on agar-agar tubes and incubated at 37° C. for periods varying from twenty-four to forty-eight hours. Special notice was taken as to whether the favourable progress of healing corresponded with the disappearance of "rod bacteria" in cases where they were present at the outset, and a plentiful growth of staphylococci. It is to be noted that Mr. Stoker in his paper mentions that staphylococci are favourable and "rod bacteria" unfavourable micro-organisms when present in a wound undergoing oxygen treatment. He also mentions that soon after the application of oxygen, and when healing sets in, that it is accompanied by a disappearance of the "rods," but not of the staphylococci, which continue to grow until healing is complete. No attempt was made to classify these "rod bacteria." The majority were short motile rods with rounded ends, growing well on any ordinary medium, and producing liquefaction in gelatin.

[1] Brit. Med. Jour., Oct. 24th, 1896.

Between February 19th and April 3rd seven cases of chronic ulcers, all specific except one, were put under the oxygen treatment. The surfaces of the ulcers were attended to in the manner described by Mr. Stoker in his paper. All the patients were men under the age of thirty years, and most of them were in a feeble state of health, emaciated, and broken down from the effects of constitutional disease and service in India, and were not good subjects to respond to any treatment. Notwithstanding the inferiority of the material to work upon, marked improvement took place in all at an early stage; pain was diminished, the discharge became less, "rod bacteria" disappeared, and staphylococci flourished all the time.

CASE 1.—This patient suffered from a specific ulcer of the leg of four months' standing. On Feb. 19th treatment was commenced with half oxygen and half air. Improvement was noted on the third day and continued until March 13th, when the ulcer had quite healed. In this case all the cultivations showed the staphylococcus pyogenes citreus only.

CASE 2.—The patient was affected by rupial ulcerations on the arms and legs of five months' standing. On Feb. 19th treatment by half oxygen and half air was applied to the left arm only, the legs and right arm having other treatment. Improvement was noticed on the second day, and on Feb. 27th all the ulcers on the left arm had healed, while for the most part those on the right arm and legs remained open. The first cultivation consisted of the staphylococcus pyogenes citreus and short "rods," and the second cultivation, taken four days after the first, showed staphylococcus pyogenes citreus only.

CASE 3.—This was a case of specific ulcer on the scalp of thirteen months' duration. On Feb. 20th pure oxygen was applied, and on the 25th half oxygen and half air were applied. The first cultivation showed staphylococci only. Healing progressed satisfactorily for the first week when it came to a standstill. After this it was noticed that a new gummatous ulcer had formed close to the old one, a circumstance which interfered considerably with its healing. On March 5th the cultivation showed a copious growth of short "rods" and only a few staphylococci. The ulcer was then sown with a pure culture of staphylococcus pyogenes citreus. On the 14th, owing to the predominance of short "rods" in the cultivations, the ulcer was again sown with a pure culture of staphylococcus pyogenes citreus. On the 20th the improvement began and the cultivations at this time showed a plentiful growth of staphylococci and a few "rods" only. On the 28th improvement was again at a standstill and the cultivations showed "rods" only. On April 1st improvement again set in and continued up to April 18th, the date of the last observation. All the cultivations after April 1st showed staphylococci only. In this case delay in healing was accompanied by the presence of "rods" in the cultivations, and when progress set in these diminished and at last disappeared.

CASE 4.—In this patient several syphilitic ulcers were present on the arms, the legs, and the face, of ten months' duration, those on the legs being the worst. The patient was in a very feeble state of health and greatly emaciated. On Feb. 28th treatment by half oxygen and half air was applied to a large ulcer on the right instep. Cultivations showed a mixture of short "rods" and staphylococci. Cultivations from another ulcer on the right knee which was being treated in the ordinary way showed a mixture of short "rods" and staphylococci. By March 6th both sides had improved. Cultivations from the ulcer on the instep showed staphylococci only, and from the ulcer on the knee a mixture of "rods" and staphylococci. On the 13th oxygen was applied to the ulcer of the knee. On the 18th both ulcers were improving and the cultivations from both showed staphylococci only. The oxygen was then stopped on account of the patient being so weak and irritable that he could not bear the necessary restraint for the continuous application of the treatment.

CASE 5.—This patient suffered from three ulcers on the shin of four weeks' standing, over a large cicatrix and caused by a fall. On March 13th, half oxygen and half air were applied. Cultivations showed a plentiful growth of "rods" and a few staphylococci. On the 16th, the ulcers had healed. Cultivations were made on the 15th and showed a plentiful growth of staphylococci and a few "rods" only.

CASE 6.—This case was one of gummatous ulcerations on the right shin and instep of four months' duration. On March 1st, half oxygen and half air were applied. No cultivations were made before the oxygen treatment.

Hosted by Google

Improvement set in after two days' oxygen, and on April 18th the ulcers had almost healed. Cultivations all showed staphylococci only, all having been taken after exhibition of the oxygen.

CASE 7.—This patient had lupus of the nose and face of nearly three years' standing. Scraping was done two days before the oxygen was commenced. On March 28th, half oxygen and half air were applied. No cultivation was made before the use of oxygen. By April 3rd there was marked improvement in the ulcers. Cultivations showed a plentiful growth of staphylococci only. By the 5th all the ulcers had closed.

In all the foregoing, with the exception of Case 5, the ulcers were of a very chronic character and had shown great resistance to other methods of treatment. In all the cases improvement was noted in from two to four days after the application of the oxygen gas, and with the exception of Case 3 the improvement was uninterrupted.

A complete explanation as to how this improvement was brought about is at present difficult to give. Possibly the oxygen acts in one or more of the following ways: (*a*) diminution of irritation—any dressing applied to an open sore causes more irritation than a mixture of oxygen and pure air; (*b*) direct stimulation without irritation; (*c*) the oxygen may oxidise the toxins produced by micro-organisms in the surface of the ulcer—this may apply more especially to the toxins produced by bacilli when present; and (*d*) as stated by Mr. Stoker, the oxygen has possibly a selective power in its action on micro-organisms present in the ulcer, encouraging staphylococci, which then outgrow the bacilli. Some of the foregoing points are at present under investigation. Here, as yet, we have only the practical results of a few cases to go by, all of which are in favour of the oxygen treatment.

Netley.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ON HOLOCAINE IN OPHTHALMIC SURGERY.

BY ROBERT BRUDENELL CARTER, F.R.C.S. ENG.,
CONSULTING OPHTHALMIC SURGEON TO ST. GEORGE'S HOSPITAL.

A FEW months ago I recorded in THE LANCET a trial of eucaine as an anæsthetic in ophthalmic surgery, but I found on further use that it was not free from certain disadvantages. The first application to the conjunctiva was apt to be acutely painful, the smarting continuing with some severity for several minutes in some persons, while different specimens of the drug appeared to differ in their power of producing it. I have been told that a modified preparation which has since come into the market, and is sold as "Eucaine B," is not painful, but I have no personal experience of its effects.

On March 27th in the present year a paper was read before the Belgian Academy of Medicine by Dr. Deneffe of Ghent on a new alkaloid called holocaine, which he described as an effective anæsthetic for ophthalmic purposes, and for which he claimed many advantages over cocaine. He said that by applying a drop of a 1 per cent. solution to the eye three times, at intervals of fifteen seconds, complete anæsthesia would be established in three minutes, without pain, without change in the diameter of the superficial vessels, without dilatation of the pupil, and without paralysis of the accommodation. These results were described as constant. As soon as I read Dr. Deneffe's paper I made an endeavour to procure the holocaine, but there seemed to be none in London. Ultimately, Mr. Rogers, of 327, Oxford-street, obtained for me a supply, and last week I was enabled to use it. In the meanwhile Dr. Gutmann had contributed a paper on the new alkaloid to the *Berliner Klinische Wochenschrift*, and, while confirming what had been said by Dr. Deneffe, he mentioned as an additional advantage that it did not act injuriously upon the corneal epithelium. But he also mentioned that the solution could only be used as an application to the conjunctiva, being actively poisonous if injected under the skin (*die subkutane Injektion zu starke Giftwirkung bedingt*), and that it could not be sterilised in vessels of alkaline glass, as it became turbid when heated in them. He advised that it should only be heated in porcelain vessels.

I received a supply of holocaine last week, and used a 1 per cent. solution in the manner described by Dr. Deneffe, having first applied some to my own eye and found that it gave no pain. Four applications were made to the patient in the course of a minute; and at the end of four minutes from the first of them I performed cataract extraction with iridectomy. The patient was unconscious of the first incision, and was barely conscious of the iridectomy, not flinching or moving the eye on account of it. The section healed perfectly by the first intention. A day or two later I used the same solution before slitting up the lacrymal canaliculus, and rendered the little operation absolutely painless. As asserted by Dr. Deneffe, there was no action upon either the conjunctival bloodvessels, the pupil, or the accommodation; and I cannot but think that the new agent will be found highly useful in ophthalmic practice. The promptitude of its action is alone of no inconsiderable advantage.

Harley-street, W.

FUNCTIONAL ACTIVITY OF MAMMARY GLAND IN AN INFANT.

BY ERNEST S. HAWTHORNE, L.R.C.P., L.R.C.S. IREL.

THE following case may prove to be of interest to readers of THE LANCET. A woman consulted me on March 11th about her baby girl and stated that when the child was six days old she observed her to be very peevish and difficult to pacify, and that when she touched the child's breasts she would scream piteously. She examined the breasts and found them to be enlarged and painful. She then squeezed them, when about two teaspoonfuls of whitish fluid oozed out from each nipple. The child then became quite quiet, and continued so until the evening, when once more she showed evidence of pain. The mother again examined the breasts and found them in a similar condition to that of the morning, so she again applied pressure and with a like result. Thus, she continued (to use her own words) "milking the breasts" every day for five days, when she consulted me. I examined the child's breasts and found them enlarged to about the size of an orange cut in half; the nipples were prominent, and on squeezing them a fluid resembling the mother's milk in appearance escaped. The child did not seem to be in any pain whilst applying the pressure, and I was able to obtain about three drachms of fluid from both nipples. I applied a small belladonna plaster over both breasts, with the result that they are now in a normal condition.

Georgetown, Queensland.

NOTE ON AN UNUSUALLY HEAVY HEART.[1]

BY G. A. REID, M.B. ABERD.,
ASSISTANT MEDICAL OFFICER, COUNTIES' ASYLUM, CARLISLE.

THE weight of the heart in the following case merits, in my opinion, its being put on record. A man, aged thirty-one years, was admitted into the Cumberland and Westmorland Asylum in December, 1896. He was 68 in. in height and 148 lb. in weight. He was known to have suffered from heart disease for nearly three years. He had been a heavy drinker, and was said to have contracted syphilis, but had never had rheumatism. At one time he competed frequently in foot-races. On admission he showed all the symptoms of marked cardiac disease; his face was pale and anxious-looking, he suffered from orthopnœa, and he had severe anginal attacks, which were alleviated by the inhalation of nitrite of amyl; his pulse was 132, and of the "water-hammer" variety; the apex beat, which was diffused and heaving, was markedly displaced downwards and to the left, and was in the seventh interspace one and a half inches outside the nipple line; the area of cardiac dulness extended from the third rib downwards and from the right sternal margin outwards to the

[1] A paper read at a meeting of the Border Counties Branch of the British Medical Association at Kendal on April 30th, 1897. The heart was exhibited.

Hosted by Google

apex beat; a mitral systolic and double aortic murmurs were present; there was no dropsy. The mental symptoms were excessive nervousness, vague anxiety, irritability, and sleeplessness, and, in reality, were greatly the result of the heart disease. He remained in very weak health, and died rather suddenly in bed on April 28th, sixteen weeks after admission. It is unnecessary for my purpose to give a detailed account of the post-mortem appearances, but a complete examination was made, as in each case of death in the asylum since 1867. The heart was free in the pericardial sac and all its cavities were distended with blood. The whole organ was dilated and hypertrophied, especially the left ventricle, its walls measuring from three-quarters to one inch in thickness. The aortic valve was incompetent; the other valves were healthy. The cone diameters were: T 1·6, P 1·25, M 1·6, A 1 35. The base of the aorta was dilated and atheromatous, and the coronary orifices were much narrowed. The heart muscle was pale and there was a considerable external deposit of fat. The organ weighed 41 ounces. The lungs were free in the pleural cavities and healthy. The liver was much congested and weighed 69 ounces. The kidneys were large and pale, weighing 6½ ounces and 7 ounces respectively, and showed no cortical atrophy. The other organs were healthy. There were a few ounces of clear fluid in each serous cavity.

In the records of necropsies performed in this asylum since 1863, now embracing nearly 1400 cases, the two heaviest hearts previously noted weighed 31 ounces and 31½ ounces. Delafield and Prudden have placed on record one heart weighing 50 ounces, and Dulles another weighing 48 ounces. So far as I can ascertain from the literature on the subject at my disposal, no other heart over 40 ounces in weight has been recorded. It should be borne in mind that the size of the heart is said to bear a relationship to the size of the individual. In this case the heart was immense in proportion.

GUY'S HOSPITAL.

CHRONIC OSTEITIS OF THE TIBIA TREATED BY DRILLING THE BONE.

(Under the care of Mr. DAVIES-COLLEY.)

MEDICINAL treatment for the pain of osteosclerosis is frequently extremely unsatisfactory, and trephining, which has been employed, is for such an ailment an unnecessarily severe procedure. "Linear osteotomy" has been performed for the condition, having been introduced by Erichsen. This consists in sawing the bone with a Hey's saw in the line of a skin incision; it gives great relief to the tension; but the method employed in the following case is certainly more simple than either trephining or linear osteotomy, as no skin incision is required, and it has the additional advantage of assisting greatly in the diagnosis of more deeply-seated mischief should it be present. For the notes of this case we are indebted to Mr. H. W. Dudgeon, clinical assistant.

A woman, aged twenty-six years, married, was admitted into Guy's Hospital on March 31st, 1897, complaining of pain in the lower and inner part of the right leg. In her family history the only fact of importance which could be elicited was that one of her brothers had died from pulmonary phthisis. She herself had had no illness previously to the present one. When seventeen years old (nine years previously) she was troubled with pain in the lower and inner side of the right leg, and this pain was especially severe at her menstrual periods. It had continued up to the time of her admission, but with varying severity. Four years previously she married, and a year and a half later, after the birth of her first child, it was noticed that the right leg, especially in the lower part, was swollen. As time went on this swelling did not diminish, but rather increased, and when her second child was born it was more marked still. On examination there was no sign of disease elsewhere than in the right leg, all the organs being healthy. The urine was normal. There was no evidence of congenital syphilis. Occupying the lower third of the right leg on the inner aspect was an obvious swelling. Its margins were ill defined, as it blended gradually with the unaffected bone above; its surface was smooth, and although the enlargement was obvious the prominence was not great. The circumference of the right leg taken over the most raised part of the swelling was seven and three-quarter inches; on the left side the circumference taken at the same level was six and three-quarter inches. The swelling was firm, and evidently due to enlargement of the tibia. Tenderness on pressure was complained of over the whole extent of the swelling. As the patient had been lying in bed there was then no œdema, but she said that it returned immediately she got about, and that if she did much walking it became very marked. She complained very much of pain, which was especially severe at night, and was not at all relieved by the rest in bed. On April 2nd, the skin over the lower third of the tibia having been carefully cleansed, Mr. Davies-Colley drilled holes through the skin into every part of the thickened bone. The drill was used thirteen times in all. No pus escaped by any of the openings, and no cavity was found in any part of the thickened bone. The wounds were dressed with sal-alembroth gauze and the limb was placed in a Bavarian splint. During the following night the patient complained of some pain in the leg, but by the help of a hypodermic injection of morphia she obtained a fair night's rest. On the 5th she had at intervals a good deal of pain. The splint was cut open. On the 11th the pain at times was still severe, but on the whole it was better. The temperature had on several occasions been a little above normal, but the highest point reached had been 100 6° F. On the 12th the pain was decidedly better, being both less frequent and less severe.

Remarks by Mr. DAVIES-COLLEY.—This case of chronic osteitis of the lower third of the tibia I suspect to be due to inherited syphilis. Before operating I was uncertain whether the chronic inflammation was around a central sequestrum or abscess, or whether it was a case of sclerosing osteitis. In such cases I think the best plan is to explore the whole of the thickened bone by means of a brad-awl or Archimedean drill without making any preliminary incision through the skin. If at any point pus escapes, or a cavity is found in the bone, it is easy to make an incision, and to open up the abscess or sequestrum cavity with a gouge or trephine. Should no such cavity be found the case is probably one of osteosclerosis, and much benefit is usually obtained from the relief of tension, and possibly also from the admission of healthy granulation tissue into the interior of the bone through the drill holes. Although the thickening of the bone still remains, the patient is now free from the severe nocturnal pain from which she had suffered.

THE name of Mr. Richard Rogers, L.D.S. R.C.S.I., dental surgeon to the Cheltenham General Hospital, has been added by the Lord Chancellor to the Commission of the Peace for Gloucestershire, on the recommendation of the Lord-Lieutenant (the Earl of Ducie).

MEDICAL, SURGICAL, AND HYGIENIC EXHIBITION.—With the object of showing the progress that has been made during the sixty years' reign of the Queen in the "manufacture of chemical preparations for medical purposes, surgical instruments and appliances, food products, sanitary compounds and apparatus, and the literature bearing on the science and art of medicine and surgery," an exhibition is to be held in the Queen's Hall, Langham-place, W., from the 26th to the 30th July next, under the auspices of the Medical, Surgical, and Hygienic Exhibitors' Association. A pathological and anatomical museum is to be a feature of the exhibition, and only those exhibits that "either directly or accessorily appeal to medical men as being of necessity or utility to them in the pursuit of their profession" will be admitted. Invitations and admission cards will be sent to members of the profession throughout the United Kingdom whose names appear in the Medical Register for the current year. An orchestra has been engaged to give selections of instrumental music in the afternoons and evenings during the period of the exhibition.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Ligature of the Subclavian Artery for Aneurysm.—Ligature of the Carotid Arteries for Tonsillar Hæmorrhage.—Irreducible Hernia.

A MEETING of this society was held on May 26th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

At the commencement of the meeting the President proposed that a loyal address should be drawn up and forwarded to Her Majesty conveying the congratulations of the Royal Medical and Chirurgical Society on the celebration of her Diamond Jubilee. He remarked that in 1840 the Queen as patron signed the book of the society, following the precedent set by her predecessor, William IV. The motion was carried by acclamation, and the book containing the Royal signature was handed round for the inspection of the Fellows.

Mr. H. H. CLUTTON read a paper on a case of Subclavian Aneurysm successfully treated by Ligature. The case was one of an aneurysm of the third part of the right subclavian artery, for which the first part of the artery was ligatured twice, and a few days after the second occasion a distal ligature was also applied to the first part of the axillary artery. The patient, a spare, healthy man, fifty-four years of age, was seen by Dr. Sharkey in February, 1896, and sent to him (Mr. Clutton) with the statement that the heart and aorta were free from any obvious signs of disease. There was a small sacculated aneurysm in the third part of the right subclavian artery reaching from the outer border of the scalenus anticus to the clavicle. On March 18th, 1896, a ligature prepared from goldbeaters' skin was applied on the proximal side at the junction of the first and second part of the subclavian artery. The ligature was tied by means of the "stay-knot" recommended by Ballance and Edmunds with sufficient tightness to arrest the circulation, but without rupturing the coats. The superior intercostal artery was also tied at the same time and in the same manner. At the end of five or six weeks the aneurysm and the radial artery were pulsating as they did before the operation. This was probably due to the ligature becoming absorbed. On June 10th the first part of the subclavian artery was exposed and tied with floss silk on the proximal side of the first ligature. The internal mammary and thyroid axis were also tied at the same time. The stay-knot was employed for each ligature, and the walls of the vessels were approximated without sufficient tightness to rupture the coats. Pulsation in the aneurysm and in the radial artery ceased as the ligature on the main vessel was being tightened. On June 17th the aneurysm was again pulsating. The first part of the axillary artery was therefore immediately tied in the same manner with floss silk, so as to cut off all the collateral vessels from the intercostals in the axilla. After this operation the aneurysm ceased to pulsate and gradually disappeared, so that the patient left the hospital on Aug. 8th without any swelling above the clavicle. Mr. Clutton considered it probable that if the first ligature had been of silk instead of an animal material the subsequent operations would have been unnecessary.—Mr. BARWELL remarked that until the last few years ligature of the subclavian artery had only rarely been undertaken. He was glad to see that Mr. Clutton supported the view which he (Mr. Barwell) had advanced fifteen years ago, that it was dangerous to rupture the coats of a vessel so near the heart as the subclavian artery, as it was not safe to trust the vessel with only part of its coats exposed to the strong pulsation unavoidable in that position. For even if the ligature held there was great risk that, if the middle coat was torn and retracted, an aneurysm might form at the seat of the ligature. He had seen the ligatures of goldbeaters' skin, but had no personal experience of their use and would not expect that they would be sufficiently firm to ensure occlusion of the artery. It was a difficult matter, requiring experience and delicacy of touch to judge the exact amount of force necessary to completely arrest the pulsation without rupturing the coats. He agreed with Mr. Clutton that, owing to the short length of artery available and the high arterial pressure, it was not safe to ligature the artery in two places and divide it.—Mr. BERNARD PITTS said that he had met with a similar case, and had operated on it at St. Thomas's Hospital a short time ago. The man had an aneurysm involving the second and third part of the right subclavian artery and also a cardiac lesion. He cut down on the first part of the subclavian artery and had no difficulty in exposing and ligaturing it with a floss silk ligature. He endeavoured, unsuccessfully as it proved, to avoid rupturing the coats. Owing to the encroachment of the tumour it was not possible to find and ligature the branches of the vessel. The pulsation and pain returned after a short time, and Mr. Ballance, in his absence, explored the site of the ligature and found a swelling, which afterwards proved to be an aneurysm, at the proximal side of the seat of the ligature. Mr. Ballance ligatured the first part of the axillary artery, but hæmorrhage occurred a few weeks later from the site of the exploration, and it was found that at the first operation the coats of the artery had been ruptured owing to their being unusually soft, and that an aneurysm had formed on the proximal side of the ligature. There was no suppuration after the operation in this case.

Mr. CLUTTON also read a paper on a case of Pharyngeal Abscess followed by Hæmorrhage, and treated by Ligature of the Carotid Arteries. The case was one of very severe hæmorrhage from an abscess in the roof of the pharynx above the right tonsil, which was eventually successfully arrested by the ligature of the common external and internal carotid arteries. A man, aged twenty-eight years, a victualler by trade, was admitted into St. Thomas's Hospital, under Dr. Sharkey, on June 20th, 1896, for a "sore-throat" and general pains. The day after admission he bled rather profusely from an abscess in the pharynx above the right tonsil. On the 24th the soft palate was divided for the purpose of a complete examination of the abscess. A hole was then found passing through the wall of the pharynx into the tissues of the neck, from which rapid oozing took place. This opening was enlarged and the cavity plugged with cyanide gauze, as it was thought from the character of the hæmorrhage that the bleeding might be from the internal jugular vein. During the night following this operation he bled so profusely that no doubt could be entertained as to the hæmorrhage being from a large artery, probably the internal carotid. The next day, the 25th, the bifurcation of the common carotid on the right side was exposed, and a goldbeaters' skin ligature applied by means of a "stay-knot" to the common carotid and its two branches. A saline infusion of two pints was given whilst the wound was being closed with sutures. The wound in the neck healed by first intention, and the abscess cavity in the pharynx was found by digital examination to have closed on July 16th. He had no further hæmorrhage after the ligature of the carotid arteries, and left the hospital for a convalescent home on July 25th. Considering the difficulties in determining the exact source of hæmorrhage when it occurred from a pharyngeal abscess, Mr. Clutton considered it to be the safest practice to tie both the external and internal carotid arteries, as well as the common carotid, for all three arteries were reached through the same incision at the bifurcation. The necessity for tying two of them had been well shown by Mr. Pitts' paper in the "St. Thomas's Hospital Reports," vol. xii., and the addition of the third scarcely increased the length of the operation.—Mr. PITTS said that fifteen years ago a patient was admitted into St. Thomas's Hospital, in whom a discharge of pus suddenly occurred from the right tonsil. A few days afterwards there was considerable hæmorrhage, which soon stopped, but a few nights later the patient brought up about a pint of blood, and ligature of the common carotid artery was hastily performed. Twenty-four hours later profuse hæmorrhage recurred and proved rapidly fatal. This showed that ligature of the common carotid alone could not be relied on. He made experiments on the cadaver, and found that if glass tubes were put in the internal and external carotid arteries of one side and coloured fluid were injected from the opposite common carotid artery the fluid appeared almost immediately in the external artery, and also, though much later, in the internal artery. In his case the source of hæmorrhage had proved to be the internal carotid, and he had been led from his experience in this case to insist on the ligature of at least the common and external carotid arteries in such a case.—Mr. HARRISON CRIPPS

Hosted by Google

said that some years ago, being dissatisfied with the plan of ligaturing the common carotid, he also had been led to experiment by injections on the cadaver. He found, however, that if he divided a branch of the facial branch of the external carotid and injected from the opposite common carotid that the fluid escaped from the proximal end of the cut artery, and he attributed this to regurgitation along the internal carotid by way of the circle of Willis. He had collected sixty-eight cases of ligature of the common carotid and had been struck with the high mortality, largely from brain symptoms, occurring immediately or a few days after ligature, or from secondary hæmorrhage, in most cases due to regurgitation down the internal carotid, so that ligature of the common carotid was a very formidable operation. Out of all the cases that he had collected there was clear evidence only in one that the internal carotid was the source of the hæmorrhage, and when that occurred death would probably take place at once, so that the question of operation did not arise. He thought that in most cases ligature of the external carotid would suffice and was much less dangerous than ligature of the common trunk.

Mr. WARRINGTON HAWARD read a paper on Irreducible Hernia. The paper was based upon an analysis of eighty-five cases in which an operation was performed for irreducible hernia. The cases were tabulated so as to show the sex and age of the patients, the situation of the hernia, the duration of the hernia and of its irreducibility, the occurrence of strangulation, the contents of the sac, the cause of irreducibility, the treatment adopted, and the result. The dangers of irreducible herniæ were described and illustrative cases quoted. The conditions on which irreducibility depended were then considered and arranged as follows: thickened and adherent omentum, 31 cases; adhesion of omentum to sac, 34 cases; twisting of omentum, 1 case; cysts in omentum, 1 case; adhesion of intestine to sac, 12 cases; adhesion of coils of intestine, 4 cases; large amount of intestine, 3 cases; and other causes, 5 cases. In a few cases more than one of the above causes of irreducibility were present. It was shown that in nearly every case these conditions are such as are remediable only by operation. From the facts and arguments adduced the following conclusions were drawn:—1. That irreducible hernia is a condition of serious danger, the gravity of which increases with its duration or neglect. 2. That the application of a truss upon an irreducible hernia is not only useless, but harmful. 3. That irreducible herniæ which consist wholly or in part of bowel are very apt to become strangulated. 4. That herniæ consisting wholly of bowel, upon which no truss has been worn, may (even when of large size and of considerable duration) generally be returned by appropriate treatment. 5. That of the cases of hernia in which proper treatment fails to obtain reduction the great majority are irreducible because of adhesions of, or changes in, the protruded viscera—conditions which are remediable only by operation. 6. That the most common cause of irreducibility is the presence in the sac of adherent omentum. 7. That the presence of irreducible omentum in the sac of a hernia is a source of constant danger, which can, nevertheless, be remedied by an operation of extremely small risk. 8. That herniæ containing irreducible bowel are more dangerous than those containing only omentum, and that as the danger of operation increases with the magnitude of the hernia and with the occurrence of adhesions these herniæ should be operated upon as soon as they are proved by the failure of proper treatment to be irreducible.—Mr. A. E. BARKER endorsed all the conclusions at which Mr. Haward had arrived. There was one form of irreducible hernia with which he had met three times in about 200 operations for the radical cure of hernia—viz., a hernia of the sigmoid flexure. The bowel in these cases had been extremely difficult to reduce, and he found that the best procedure was to strip the sac bodily off with the intestine and return it.—Mr. MACREADY was hardly able to assent to the conclusion that operation was always indicated in these cases. He thought that properly applied pressure by means of a truss would succeed in many instances in reducing the hernia. Two-thirds of the inguinal and half of the femoral herniæ that he had treated in this way had been reduced. He thought that there was unnecessary fear lest the pressure of a truss should cause adhesions, and held, on the contrary, that it favoured the absorption of adhesions.—Mr. HAWARD, in reply, said that he had not met with the cases of hernia of the sigmoid flexure described by Mr. Barker. He thought that the pressure of a truss had often done harm in these cases, and that had induced him to bring forward this paper. He had used elastic pressure, combined with purgation, low diet, and elevation of the end of the bed, and had found it successful chiefly in patients who had not previously worn a truss, which he believed to be responsible in many cases for the formation of adhesions.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—The Value of Exploratory Laparotomy.

A MEETING of this society was held on May 13th, Mr. MAYO ROBSON, President, being in the chair.

Mr. F. BOWREMAN JESSETT showed:—(1) Fibro-myoma of the Uterus—sub-peritoneal hysterectomy; (2) Fibro-myoma of the Uterus—oöphorectomy; (3) Myoma of the Uterus—double pyosalpinx, sub-peritoneal hysterectomy; and (4) Large Fibro-myoma of the Uterus, complicated with pregnancy.—The PRESIDENT, Dr. PURCELL, Dr. C. H. F. ROUTH, Dr. GODSON, and Dr. HEYWOOD SMITH made some observations, and Mr. JESSETT replied.

Dr. HERBERT SNOW read a paper on the Value of Exploratory Laparotomy *per se* in (*a*) Real and (*b*) Supposed Malignant Disease of the Abdominal Organs. Dr. Snow had been struck by the remarkable improvement in certain cases of indubitable malignant disease which followed a simple incision without any further operative procedures, and thought if future explorations were scanned in the light of expected amelioration it would be found that the peritoneum thus stimulated behaves to a certain extent as in tuberculosis. A small part of the tuberculous deposit only is removed, yet the remainder somehow disappears, and the patient becomes and continues well. In malignancy the resulting benefit has hitherto been overlooked through the common practice of sending patients home as incurable directly the wound has healed. In Case 1 a woman, aged forty-nine years, with advanced carcinoma of the sigmoid flexure, gained flesh and lost all bad symptoms, though the favourable change lasted only six weeks. Case 2 was that of a woman, aged fifty-three years, with a rapidly advancing, very vascular deposit in the omentum, secondary to scirrhus of the breast. After incision the advance was materially checked, the mass diminished in size, there was no ascitic trouble, and the woman lived eighteen months. Case 3 was that of a man, aged fifty-eight years, with extensive deposit of carcinoma along the whole posterior surface and most of the greater curvature of the stomach; great improvement took place after incision, but the patient was soon lost sight of. Case 4 was that of a man, aged sixty-four years, with a large sarcomatous mass infiltrating both recti; exploration was made in June, 1896. The growth had diminished in size, the man had no bad symptom, and was now able to work regularly as a sawyer. Case 5 was that of renal exploration for a growth thought to be cancerous and infiltrating the lumbar muscles. All bad symptoms had subsequently vanished. Case 6 was that of a woman, aged forty-eight years, with cancer of the gall-bladder. After exploration she stated that she "felt better and more free from pain than she had done for months." She went home and has since succumbed. From a recent paper by Mr. Leonard Bidwell two cases of diffused peritoneal cancer were quoted in which very pronounced benefit similarly followed laparotomy. Others were cited in which the diagnosis of abdominal "lumps" was shown to contain, in even the ablest hands, a strong element of uncertainty. Dr. Snow concluded that routine exploration should be resorted to in every case of supposed abdominal cancer for two reasons: (*a*) the possibility of error; and (*b*) the fact that as a mere matter of treatment this step always improves, and often materially checks, the advance of the disease, permitting scope for the administration, on which he placed the greatest reliance, of opium with cocaine.—The PRESIDENT said that he had himself operated on cases where, on opening the abdomen, he believed that he had to do with ineradicable malignant disease and had closed the abdomen without proceeding further, yet the patients had got quite well. In one case the operation was in the region of the gall-bladder; before she left hospital the patient was already much better; and now, several years after the operation, she remained quite well. Last week he had a somewhat similar

Hosted by Google

case; but remembering the previous case he proceeded with the operation and found an enormous gall-bladder, from which he removed eighty stones. In another case, with ascites, on opening the abdomen he thought the patient had malignant disease. The patient got well; it was probably tuberculous. Increased experience would, he thought, show that many of these cases were not malignant.—Dr. CLEMENT GODSON related a case seen by the late Sir Spencer Wells which he diagnosed a tumour of the spleen, and wished to remove. Later the patient was seen by Mr. Meredith in consultation with Dr. Godson, who agreed that it was more probably an enlarged kidney. An exploratory incision was made, and it was found to be such, but so adherent to the surrounding parts that its removal was impossible, so the wound was closed. From that time the patient's condition improved, and she now, several years after, complains of nothing.—Dr. MACNAUGHTON-JONES thought the main point was that most of the cases were not malignant. He saw a case with ascites; some said it was ovarian and some said not. The patient was tapped, but the fluid returned. On making an exploratory incision a hard, enlarged lobe of the liver was found and the abdomen was closed. The patient had since married and borne children.—Dr. PURCELL had a case in which there was a mass in the left iliac region and ascites (which he believed always occurred with malignant disease involving the peritoneum). On opening the abdomen a tumour of the bowel was found, not occluding it, but adherent to everything. He closed the abdomen, and the patient was now, eighteen months later, in good health.—Mr. BOWREMAN JESSETT thought the title of the paper was somewhat a misnomer, since Dr. Snow had not the opportunity in all the cases of saying whether the tumour was malignant or not. In one case he saw a woman with a large tumour; she had vomiting and watery motions. Her medical man diagnosed cancer of the liver, and Sir William Jenner and Dr. Ramskill, who saw her, confirmed the diagnosis. A copious sweet-oil enema caused that tumour to come down into the bedpan. In one or two other cases he had had a similar experience, and in such cases a similar improvement would have followed abdominal section. Dr. Snow had suggested that in many cases gastro-enterostomy might be supplanted by a simple cœliotomy, but he did think that equally good results would follow.—Dr. C. H. F. ROUTH thought that there was often no harm in making an exploratory incision, for in tuberculous cases especially a cure might follow. They did not know how this was brought about, but it might be due to the action of the air.—Mr. J. WALKER SMYTH had had two cases similar to those of Mr. Jessett; in one an enema was given, with the same result. The other was a man with a lump over the pubes; with the catheter a quantity of urine containing pus was drawn off; the tumour disappeared and the man got well.—Dr. HERBERT SNOW, in reply, said that his paper involved two points: (*a*) the advisability of an exploratory incision in cases of doubt; and (*b*) the undoubted improvement that followed this in some cases of genuine cancer. The President's cases fell into the first category. In cases of the second class, the point he wanted to raise was whether they might not count on an improvement for some weeks or months. He had cited no cases which got ultimately well; but in all there was improvement for a time.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Bacteriological Diagnosis of Enteric Fever.—Mesenteric Cysts. — Triplet Placentæ. — Transposition of the Heart.

A MEETING of this society was held on April 30th, Dr. BRAITHWAITE being in the chair.

Dr. TREVELYAN read a paper on the Bacteriological Diagnosis of Enteric Fever, including the examination of the fæces, urine, and blood. The technical difficulties, and especially the time required, were serious disadvantages in the examination of the fæces. The presence of the enteric fever bacillus in the urine from two cases of enteric fever was demonstrated, and the importance of dealing efficiently with the urine from the point of view of preventing the spread of the disease was emphasised. Widal's serum test for the examination of the blood was exhibited, and the methods recommended by Delépine and by A. Fraenkel were described as being easy to carry out.

Mr. MOYNIHAN read a paper on Mesenteric Cysts, describing two cases upon which he had operated. The first patient was a female, eighteen years of age, who suffered from acute intestinal obstruction. There was an ill-defined swelling to the right of the linea alba. A chylous mesenteric cyst which caused kinking of the gut was opened, stitched to the parietal peritoneum, and drained, the recovery being uneventful. The second case was a boy, aged seven years, who presented symptoms of acute intestinal obstruction. On opening the abdomen a very large mesenteric cyst containing forty-two ounces of pure chyle was exposed. The pedicle of the cyst was cut through, the peritoneal edges inverted and stitched, the cyst being removed. The boy died about two hours after the operation. An excessive amount of indican was present in the urine. The diagnostic signs were pointed out to be:—(1) the presence of a cyst in the abdomen, at first laterally placed, but becoming with increasing size more and more central; (2) resonance above, below, and across the tumour (the three "diagnostic signs" of Tillaux), the latter being due to the portion of gut attached to the mesentery involved; and (3) extreme mobility in all directions. The methods of treatment mentioned were:—(1) opening and drainage of the cyst; (2) removal of the cyst by cutting through the layers of peritoneum in the pedicle; and (3) enucleation.

Mr. C. J. WRIGHT showed the Placentæ from a case of Triplets. There was one large placenta with two cords and a second smaller one with one œdematous cord. The amniotic bags were separate. This was the mother's second confinement; she was twenty-five years of age, and was one of a family of thirteen, amongst whom there had been twins on three occasions. Her mother was a twin, and also her grandmother, so that there were multiple births through four generations. The presentations in this case were vertex for No. 1, transverse (delivered by podalic version) for No. 2, and face for No. 3. No. 1 was alive on the fifteenth day; the others died on the eleventh and twelfth days respectively.

Dr. WARDROP GRIFFITH showed a girl, aged seven years, with Transposition of the Heart. There was no transposition of the liver. Cyanosis and dyspnœa had been present from the age of three years. There was cardiac hypertrophy with a loud bruit, with its maximum in the pulmonary area—in this case the third right costal cartilage. Pulmonary stenosis was diagnosed, with possibly a deficiency of the cardiac septum.

EDINBURGH OBSTETRICAL SOCIETY.

Vaginal Hysterectomy.—Interstitial Pregnancy.

A MEETING of this society was held on May 12th. In the absence of the President Dr. JAMES RITCHIE occupied the chair.

Dr. FREELAND BARBOUR read a paper on Vaginal Hysterectomy by Doyen's Method. He said that the first extirpation of the prolapsed uterus for cancer was performed in 1560 by Andreas A. Cruce. The non-prolapsed uterus was removed per vaginam for the first time in 1822 by Santer, of Constance; this patient recovered, but died four months later from pneumonia. In 1828 Blundell also extirpated the cancerous uterus successfully per vaginam; the patient died one year afterwards from cancer of the rectum. A year later Recamier placed the operation on a scientific footing by ligaturing the base of the broad ligaments. The next fifty years were occupied by attention to hysterectomy for fibroids. Extirpation of the uterus for malignant disease was revived in 1878 by Freund, who used the combined abdominal and vaginal operation. In two years, out of ninety-three cases there was a mortality of 73 per cent., which condemned the operation. Czerny, Schrœder, and some others were developing the technique of the vaginal method, and out of thirty-two cases they showed a mortality of only 25 per cent. The vaginal method does not exhaust the patient so much as the abdominal. Even when the ovaries are removed as well as the uterus the patient looks no worse than when a repair of the perineum has been performed. There is no risk of handling the bowels as in the abdominal method, less risk of sepsis, and free drainage is secured. A drawback is the difficulty of reaching the broad ligaments so as to control

Hosted by Google

the blood-supply. The ligature method is tedious, and, according to Hegar and Kaltenbach, the accompanying hæmorrhage is the chief cause of the mortality in this operation. The clamp method has distinct advantages. It was suggested by M. B. Freund for use in the combined operation. Spencer Wells in 1882 proposed its use in the vaginal operation, and this was put into practice by Jennings a year later. The honour of making the clamp a practical success belongs to Péan and Richelot. Doyen, of Rheims, has used it with great success, introducing new methods, if not also new principles. Péan used the clamp as a temporary or preventive measure, Doyen as a permanent means of arrest. The method of application is also different. Doyen emphasised the advantage of splitting the uterus anteriorly and showed the possibility of temporarily controlling the hæmorrhage by traction on it. The patient is prepared by repeated vaginal douching and packing with iodoform gauze. The cancerous surface should be cleansed as far as possible; some scrape the surface and apply alcohol, so as to lessen the risk of inoculation by cancer cells on fresh-cut surfaces. When the vagina is narrow, as in a nullipara, Doyen previously inserts a dilating bag. The instruments are spatulæ, scissors, strong volsellæ (like bullet forceps), and clamps. The clamps have elastic concave blades, which only meet in their entire length by the use of firm compression. This gives an effective control of all vessels in the broad ligament. Each blade is grooved to prevent slipping. The cervix is caught laterally and drawn down, and a circular incision is made with scissors through the vaginal mucous membrane. Ségend makes a lateral incision in the former, so as to facilitate the separation of the bladder, and in 400 cases has not once injured the ureter. The pouch of Douglas is now cut into by clipping with scissors, carefully guided by the finger, until the peritoneal cavity is reached. If the pouch is obliterated by adhesions the separation of the uterus anteriorly is proceeded with. As soon as the cervix is so far free the uterus is split with the scissors in the middle line anteriorly, the cut margins are caught by volsellæ and more of the uterus pulled down, and the anterior wall still further split until the utero-vesical peritoneum is reached. This is cut through, the scissors inserted, and the opening enlarged by separating the blades. The fundus is seized and pulled out and the clamps are applied. The broad ligament is caught between the finger and thumb or between the index fingers of both hands, the finger tips meeting beyond the base of the ligament, thus ensuring that no intestine is caught in the clamp. The clamp is introduced from the upper margin of the ligament downwards, so that the points of the clamp are at the wound in the fornices. It can be applied alongside of the uterus, or if the appendages are to be removed as well it is placed external to these. A smaller clamp is passed on the inner side of the large one—that is, between it and the uterus for safety. The uterus is then cut away. The handle of the clamp is now turned down so that it is in line with the axis of the vagina; this causes some twisting of the broad ligaments. Iodoform gauze is inserted between the clamps and the ends thrown round the handles of the clamps when these might injuriously press on the vulva. In the after-treatment the bladder should be emptied by the catheter for two days to prevent soiling of the vaginal tampon. Considerable pain is sometimes complained of, much more than after the ligature method has been employed, and can be met by morphia. The large clamp is removed in forty-eight hours, the smaller one twelve hours later. The iodoform gauze is extracted on the following day. A gentle douche can then be given. Usually there is not much discharge, though sloughs may come away, and considerable serous oozing may occur. The vaginal roof is well cicatrised in three weeks, and the patient is then able to go about. This method of operating has several advantages. It allows more rapid operating; the bleeding is all controlled by the traction, and no hæmorrhage is to be attended to until the final stage, when the clamp is applied; the splitting of the uterus allows it to collapse and gives a fresh hold for the forceps; the rotation of the uterus and the application of the clamp from above downwards enable the operator to more certainly get the whole ligament within the bite; the weight of the clamp keeps the broad ligament pedicles down in the vagina, preventing their retraction; the layers of the peritoneum thus become opposed and are adherent above the clamps; and the presence of the clamps favour drainage per vaginam. As compared with the ligature it has a longer convalescence, but this is more than compensated for by the greater rapidity in operating. Dr. Barbour then gave details of six cases upon which he had operated. All recovered. Five of the cases were of malignant disease of the cervix or body; one showed recurrence in three months and another in nine months; one was for prolapsus uteri. Jessett has recorded seventy cases of malignant disease with six deaths. Purcell, who performed the first vaginal hysterectomy in England for cancer, has had sixty-three operations with twelve deaths. In Germany, Fehling has collected the statistics of thirteen operators and found the mortality to be 9·1 per cent. Kaltenbach has operated on 138 cases with a mortality of 3 per cent. Cases suitable for operation only exceptionally present themselves in this country. This is in remarkable contrast to the experience of German operators. The statistics vary as regards non-recurrence. Leopold's statistics show immunity in the case of more than one-half and are very encouraging. Against this is Perri's rather pessimistic estimate that the operation is rather a palliative treatment for a longer or shorter time, the average being one year. The lymphatics play the chief part in the dissemination of cancer. The lymphatics of the uterine body pass through the upper part of the broad ligament to the lumbar glands, receiving on their way those of the ovary and tube. Those from the cervix and upper part of the vagina pass through the lower part of the ligament to the iliac or ileo-pelvic glands. Another chain runs down the round ligament to the inguinal glands. The lumbar glands cannot be palpated; the ileo-pelvic can be examined per vaginam. The inguinal glands are very rarely affected in uterine cancer. Nodules of cancer may be found separate from the original focus, which have grown within the lymphatic vessel from some epithelium carried there by the lymph stream. Mr. Stiles states that the endothelium is not affected by these cancer plugs, and says that a knife once used to cut cancerous tissue should not be used again at the same operation.

Dr. J. C. KYNOCH (Dundee) read notes of a case of Interstitial Pregnancy. The uterus was shown and was submitted to a committee for examination and report.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Exhibition of Specimens.—Strangulation of an Intraligamentous Fibro-myoma.—Ergot in Obstetrics.

A MEETING of this section was held on April 23rd, the President, Dr. LOMBE ATTHILL, being in the chair.

Mr. E. HASTINGS TWEEDY showed an Ovarian Cyst with Adhesions.

Dr. ALFRED SMITH showed a large Hæmatosalpinx with hæmatoma of the ovary which he removed from a girl aged twenty years. The external examination, taken with the history of pain, rise of temperature, &c., pointed to an appendicitis. This was negatived by finding on the bimanual examination a large tumour filling the right side of the pelvis. But it was found, while removing the tumour, that the vermiform appendix was adherent to it and lay right across the surface of it. The adhesions were numerous and rather troublesome. Recovery ensued.

Dr. W. J. SMYLY showed an Ovarian Tumour and Carcinomatous Uterus.

Dr. ALFRED SMITH and Mr. M'ARDLE read notes on a case of Broad-ligament Myoma Strangulated by Protrusion through the Inguinal Canal, and exhibited the specimen. Dr. Alfred Smith saw the case in consultation with Mr. M'Ardle, who demonstrated the large hernial opening and the tumour. The history of pregnancy, the appearance of the tumour, and its elastic feel gave the impression that the case was one of ectopic gestation, probably in the cornua of a uterus bicornis; and accordingly Dr. Smith, by permission of Mr. M'Ardle, performed abdominal section. He noticed that the handling of the tumour did not cause any rhythmic contractions. On closer inspection he found that he could differentiate two masses; one was more or less pedunculated, and was evidently the portion that had descended into the hernial sac, and the other filled the right side of the pelvis and was firmly wedged there. The two

Hosted by Google

masses were united together by a broad base. He incised the capsule to determine the nature of the contents, and found it was not a cyst, but a soft œdematous tumour, the tissue of which tore easily with the finger; he then removed the pedunculated lobe, and rapidly enucleated the remaining portion out of the fold of the broad ligament. Professor McWeeney reported the specimen as an intra-ligamentous fibroid undergoing mucoid degeneration. The points of interest were as follows: (1) the difficulty in diagnosing the tumour; and (2) the presence of an intra-ligamentous uterine fibroid in an inguinal hernial sac. The patient's recovery was rapid.—Dr. E. WINIFRED DICKSON asked if there was any bowel down together with the tumour, or if only the tumour was strangulated.—Dr. SMYLY asked if the tumour was connected with the round ligament. It would appear to him to be a likely origin of growth. He also asked why a new opening was made in the abdominal wall instead of enlarging the existing one.—Mr. M'ARDLE, in reply, said that there was no bowel down along with the tumour. It was the second time that stercoraceous vomiting had come under his notice in connexion with troubles in close proximity to the end of the ileum. He referred to a case where an œdematous ovarian tumour had pressed on the ileum causing spasm, which produced obstruction. With regard to Dr. Smyly's question about the second opening, he (Mr. M'Ardle) said that he had avoided any incision which would endanger the deep epigastric artery as well as the arteries of the rectus muscle, the patient having been for a considerable time under chloroform. Also, it was impossible to get inwards because the tumour was so large, crushing the uterus to the left side.—Dr. SMITH, in reply, said that he thought at first he had to deal with a uterus bicornis. He found that the round ligament was apparently quite right on each side.

Dr. T. MORE MADDEN read a paper on the use and abuse of ergot in obstetrics, which will be found on page 1462 of this issue.

Reviews and Notices of Books.

Atlas of Human Histology. By Dr. ARNOLD BRASS (Göttingen). With Explanatory Notes. Translated from the German by R. A. YOUNG, M.D., B.Sc. London: Baillière, Tindall, and Cox. 1897. Sixty plates engraved and printed in colours. Large 4to. Price 31*s.* 6*d.* nett.

WE have much pleasure in calling attention to this most beautiful and artistic atlas, in the production of which no pains seem to have been spared. The sixty plates contain nearly 500 coloured drawings of the various tissues and organs of the body, which could hardly be surpassed for clearness and fidelity. The sections from which they have been taken have been lent by many of the most eminent Continental pathologists, and, being obtained chiefly from newly-born infants and recently executed criminals, give a more accurate representation of human histology than most current works in this country, where the histologist has to rely largely on the lower animals for fresh specimens. The reproduction has been most efficiently done, the process having been carried out by Dr. Brass himself. Very fine plates are given showing the structure of the cell and of the principal tissues, and then the various systems of organs are taken up in their order. The sections on which most labour has been expended are those on the Sense Organs and on the Central Nervous System, and we know of no work in which such complete illustration of these organs is given. The beautiful effects obtained by the gold chloride method in the case of the cutaneous sense organs and by the Golgi silver process and by Nissl's aniline method in the central nervous organs are most faithfully reproduced. The intimate structures of the internal ear, of the eye, and of the medulla oblongata are most artistically and faithfully reproduced. The section on the Alimentary Canal is also very good and complete, but the section on the Structure of the Lung is very inadequate, and the section on the Blood is disappointing in view of the great advances that have been made in that department in recent years. But with these exceptions it is impossible to speak except in terms of the highest praise of the work. The plates are accompanied by concise descriptions of the drawings, which have been translated into excellent English by Dr. Young; the book is portable and well bound, is produced at a reasonable price, and will no doubt have a large sale among both teachers and students.

A Course of Practical Histology. By E. A. SCHÄFER, LL.D., F.R.S. Second Edition. London: Smith, Elder, and Co. 1897. 290 pp. Price 7*s.* 6*d.*

THIS book contains in a concise and portable form a vast amount of accurate information presented in a clear and well-arranged manner. After a short but adequate account of the methods of embedding, cutting sections, and drawing the appearances seen under the microscope, the devices for observing the blood under varying conditions of temperature are very fully described. A consideration of the methods for exhibiting the details of structure of the elementary tissues and of the organs of the body occupies the rest of the book. Professor Schäfer wisely avoids giving a heterogeneous jumble of methods which are multiplying daily, but selects those which he has found to give the best results, or which are of the most general applicability. The standard of excellence is throughout very high, and this is especially conspicuous in the important sections dealing with the blood and with the peripheral and central sense organs. No description of the histological appearances is given, the whole book being devoted to practical directions for the student's own investigations. The work can be very strongly recommended as being thoroughly up to date, accurate, and so clearly written that no difficulty should be experienced in following out the instructions given.

LIBRARY TABLE.

Aids to Bacteriology. By T. H. PEARMAIN and C. G. MOOR, M.A. London: Baillière, Tindall, and Cox. 150 pp. Price 3*s.* 6*d.* 1897.—This is an admirable presentation of the outlines of bacteriology. The necessary apparatus is fully described, although unfortunately not illustrated, and the methods of cultivation and staining are clearly given, the authors wisely giving only a limited number of methods, but giving those in such detail as to make it easy for anyone to follow out the processes. There is an excellent account of disinfection, of immunity, and of the preparation of diphtheria antitoxin and of Haffkine's cholera vaccine. The characters of the chief pathogenic and non-pathogenic organisms, both under the microscope, and when growing on various culture media are systematically described. The little work is well up to date, and the authors have succeeded in giving the most clear and useful account of this important subject in brief form with which we are acquainted.

Life in West London. By ARTHUR SHERWELL. Second Edition; with a supplementary chapter. London: Methuen and Co. 1897. Pp. 202, price 2*s.* 6*d.*—In our review of the first edition of this book we remarked that Mr. Sherwell did not suggest any remedies for the state of matters he described, but in the supplementary chapter to the second edition he repairs this omission. What is imperatively needed, he says, "is not fresh charitable enterprise, but enthusiastic and intelligent personal service, working ..... along the lines of existing agencies, but supplementing these, where necessary, by other careful and well-approved forms of social help." More voluntary workers is the cry of a great number of those who are set over their fellows in one capacity or another, and voluntary workers are just the hardest class

Hosted by Google

of workers to procure owing to the exigencies of modern life. If we had some kind of organisation analogous to the Florentine Brothers of Mercy, or the association described by Mr. Adderley in "Stephen Remarx" we should be a long way towards the solution of the problem, but at present we are far from the goal. Mr. Sherwell suggests the formation of a small but expert "watch committee" to report upon cases of overcrowding; this is a measure which might easily be brought about. His second suggestion he owns is a most difficult one to carry out—namely, that "fashion" with regard to its malign influence upon seasonable trade should be resisted, but how this point is to be gained we must confess we do not see. Thirdly, he wishes for the establishment of well-conducted and rational places of amusement. That it will be a long time before any of these suggestions are got into working order we have no doubt, but the mere fact that some one has formulated the kind of thing wanted is no small step towards such a desirable end.

The Climate of Bournemouth in Relation to Disease, especially Phthisis. By A. KINSEY-MORGAN, M.D. Durh., Honorary Medical Officer, Royal Victoria Hospital, Bournemouth. Bristol: John Wright and Co. London: Simpkin, Marshall, and Co. 1897. Pp. 51.—The dryness of its sandy soil and the mildness of its climate give Bournemouth a prominent position among English health resorts, especially among those recommended for the residence of sufferers from pulmonary complaints. The sea frontage, the luxuriant pine woods in the immediate vicinity, and the care which has been bestowed on the drainage, all conduce to the salubrity of the atmosphere, while the anxiety of the townspeople to meet the requirements of invalid visitors is shown by the facts that the "Mont Dore cure" can be applied all the year round, that every form of "water cure" is obtainable, and that the open-air treatment of phthisis, as practised at Falkenstein and elsewhere on the continent, is being systematically put in force, With respect to the cure of phthisis in its early stages Dr. Kinsey-Morgan writes quite hopefully.

Several Selected Remedies against Plague and Suggestions for its Treatment. By A. PEREIRA. Bombay: Printed at the "Tatvavivechaka" Press. 1897. Pp. 31. Price 8 annas.—The Materia Medica described by Mr. Pereira in this pamphlet differ considerably from that which was recognised by his celebrated namesake, Dr. Jonathan Pereira. The work is not original, but is a translation from a Portuguese book entitled "Remedios contra Peste," published by Dr. Helvecio in 1747. The remedy from which most is expected is the "tincture of gold," made by dissolving 48 grains of chloride of gold in 1 oz. of rectified spirit; the dose is from six to ten minims. Many other medicines, however, are mentioned, pig's gall and viper broth included.

A Manual of Medical Exercises. By PERCY G. LEWIS, M.D. London: John Bale and Sons. 1897. Pp. 50. Price 2*s.*—This little book was written for the use of Dr. Lewis's patients who attend the Folkestone Medical Gymnasium. It can be recommended as giving clearly expressed and ample directions for the performance of a number of gymnastic exercises, some of them without any apparatus, and others with the aid of such gymnasium appliances as Dowd's machines, ladders, dumb-bells, the trapeze, &c.

Year-book of the Scientific and Learned Societies of Great Britain and Ireland. London: Charles Griffin and Co 1897. Pp. 270. Price 7*s.* 6*d.*—This useful and, to many persons, indispensable work of reference has now reached its fourteenth year of issue. The societies treated of are classified according to their various objects in fourteen departments, some of which are "Science Generally," "Chemistry and Photography," "Biology, Microscopy, and Anthropology," "Psychology," "Medicine," &c. The names of the officers, the places and dates of meeting, the terms of membership, and lists of the papers read during 1896 are given, together with the names of their authors. The total number of societies included in the volume is upwards of a thousand; the medical societies occupy forty-five pages.

JOURNALS AND REVIEWS.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D. Lond., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. XXI. Nos. 4 and 5. London: C. J. Clay and Sons. Price 13*s.*—The articles contained in this part are thirteen in number. The first is by Arthur Cushny and S A. Matthews on the Effects of Electrical Stimulation of the Mammalian Heart, with fifteen figures in the text. The authors give tracings showing the effects of stimulation of the heart at different periods of its action and when applied to different parts. 2. G. J. Burch: A Description of an Inductor Alternator for Physiological Experiments, with two figures in the text. 3. M. I. Newbigin: The Pigments of the Decapod Crustacea. 4. Herbert S. Jennings: Studies on Reactions to Stimuli in Unicellular Organisms especially dealing with Reactions to Chemical, Osmotic, and Mechanical Stimuli in the Ciliate Infusoria, with twenty-two figures in the text. 5. L. Hill and H. Barnard: On the Influence of Gravity on the Circulation. 6. T. G. Brodie and S. W. F. Richardson: On the Changes in Length of Striated Muscle under varying Loads brought about by the Influence of Heat, with thirty-eight figures in the text. 7. B. Moore and D. P. Rockwood: On the Reaction of the Intestine in Relationship to Intestinal Digestion. 8. B. Moore: On the Chromogen and on the Active Physiological Substance of the Suprarenal Gland. 9. T. G. Brodie and A. E. Russell: The Enumeration of Blood Platelets. They give the number 635,300 per cubic millimetres, or an average of 1: 8·5 of red corpuscles. 10. O. F. F. Grünbaum: On Intermittent Stimulation of the Retina, Part I., with three figures in the text. 11. T. G. Brodie and A. E. Russell: The Determination of the Coagulation-time of Blood, with one figure in the text. 12. E. Waymouth Reid: A Comparison of the Diffusion into Serum and Absorption by the Intestine of Peptone and Glucose, with one figure in the text. 13. E. J. Burch: An account of Certain Phenomena of Colour Vision with Intermittent Light.

Revue Philanthropique.—This is a new monthly journal of 160 pages, conducted by M. Paul Strauss, and published by Masson et Cie., Boulevard Saint-Germain, Paris. Among the twelve original articles an important one on the protection of children is contributed by M. Theophile Roussel, who has already been mentioned in our columns[1] as the promoter of the French law by which Government officials are appointed to look after persons having the care of young children not their own. Dr. Pierre Budin writes on the feeding of infants, recommending, first, suckling by the mother; secondly, suckling by a wet nurse; and failing either of these, feeding with sterilised cow's milk, generally without addition of water. Dr. H. Thulié discusses the methods of dealing with juveniles who have more or less bias towards evil courses and are in danger of becoming criminals. He considers that such persons, although not by any means imbecile, are the subject of mental infirmity, due, among other causes, to one or both of the parents being intoxicated at the time of conception.

Birmingham Medical Review.—The opening paper is by Mr. D C. Lloyd Owen, the subject being Pain in Eye Disease. It contains many useful practical hints. Mr. Lawson Tait

[1] THE LANCET, Oct. 24th, 1896, p. 1191, and Oct. 31st, 1896, p. 1263.

Hosted by Google

discusses the question, Was Robert Houston of Glasgow the first Ovariotomist? His opinion is "that Robert Houston's case (1701) was an ovariotomy in every sense of the term, and that (be it of interest and importance or not) it is the first case of that operation of which we have any record." He has occasionally met with ovarian cysts corresponding exactly to the description given by Houston of the one on which he operated; their contents are gelatinous or viscous, "will not flow through any trochar, and can be induced to get out of any sized wound only with the greatest difficulty. ..... When the abdomen is cleared, and the process is a long one, the cyst is found to be a movable bundle of shreds with a vague pelvic attachment ..... in some six or eight cases, so far as my memory serves me, there was nothing left to tie." This explains why Houston did not tie the pedicle, and Mr. Tait takes the opportunity of correcting the opinion he expressed in 1883 to the effect that he (Houston) must have seen it and tied it.

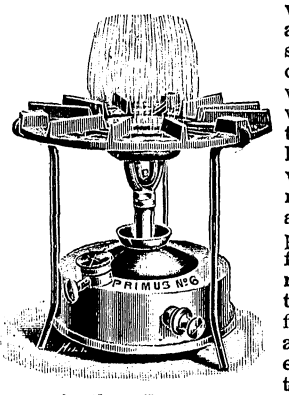
Edinburgh Medical Journal.—The opening article is a lecture on Endocarditis, delivered by Dr. Lauder Brunton. The diagnosis of this disease is based mainly on the temperature chart; when the temperature resembles that of quotidian ague, without there being any evidence of either malaria or suppuration, the case is probably endocarditis, even though there is no cardiac murmur. Dr. P. McBride and Dr. A. Logan Turner continue their papers on Naso-pharyngeal Adenoids. Altogether there are ten original contributions.

Dublin Journal of Medical Science.—An interesting and very detailed account of a case of Angina Pectoris is given by Dr. John Knott. Dr. T. P. C. Kirkpatrick has a paper on the Spread of Tuberculosis by the Milk-supply, in the course of which he refers to Professor McFadyean's observation that tuberculin is not a reliable test in the case of cattle standing in open sheds, in the slaughter-houses, and exposed to excitement.

Scottish Medical and Surgical Journal.—The principal paper is by Dr. Byrom Bramwell, being a clinical lecture on a case of Chronic Pneumonia due to the Pressure of a Small Aneurysm on the Left Bronchus. Mr. David Wallace writes on the importance of Asepsis in Urinary Surgery, giving a history of the development of opinion on the subject and an account of a case of Septic Infection which terminated in recovery. He considers that purification of instruments is insufficient to prevent sepsis. Dr. William Russell, the editor, contributes two cases of Pleural Effusion without characteristic symptoms and two of chest pain, one of which was attended by extreme surface tenderness.

New Inventions.

AN AUTOMATIC DISINFECTOR.



THIS is an ingenious and simple arrangement for attaching to the pipe down which the water travels from the cistern to the closet for flushing purposes. A hole is first made in the wall of the pipe with a drill that is provided. Next, a brass tube provided with a screw clamp and washers is inserted into the hole so made. A brass collar is then placed round the waterpipe, which holds the brass tube in position. It is then screwed up and clamped firmly. The tube thus inserted into the flush-pipe then takes a right angle ending in a brass tube about 7 in. long, which is immersed in a disinfecting fluid. The fluid recommended for this purpose is Esset's fluid, which is a cresylic resinous compound, giving with water a milky emulsion. By means of a tap attached to the tube which dips into the bottle the amount of fluid sucked into the water as it descends from the cistern into the closet-pan may be adjusted to a nicety. Once the tube is attached to the pipe and placed in position no further attention is needed. All that is necessary is to replace the bottle when empty with one that is full or to fill the empty one with fresh disinfectant. Other disinfecting agents might, of course, be substituted. We regard this apparatus as a useful and handy sanitary adjunct. It possesses the distinct advantage that it is always possible to see whether it is acting properly or not. The specimen we examined was submitted to us by Messrs. A. Granville and Co., 102, High-street, Battersea, London, S.W.

THE PERFECTION ENVELOPE.

WE have frequently animadverted upon the objectionable practice of moistening with the tongue the gum of stamps and of envelopes. This objectionable method in regard to the latter may to some extent be overcome by the use of the "Perfection Envelope," on which the gum is stuck, not on the flap itself, but on the portion of the envelope to which it becomes attached. Thus the flap contains no gum. It seems to us that the same end might be attained if the person decided to lick that part of the envelope where the flap falls, instead of the flap. On the whole, however, it is, perhaps, more convenient (if the tongue must be employed) to moisten the flap, and the gumless flap, but gummed envelope, which Messrs. J. Walker and Co., Limited, Farringdon House, Warwick-lane, E.C., have recently introduced will secure this advantage.

A WICKLESS OIL STOVE WITH SMOKELESS FLAME.

THE production of a practically colourless and smokeless flame from ordinary paraffin oil is an attainment of some importance. Considering the enormous amount of carbon in ordinary petroleum as compared with the amount in coal gas, the fact that the flame may be converted from a white sooty flame into a flame possessing the exact characteristics of the ordinary Bunsen gas flame is somewhat surprising. Still, it has been done with complete success in the oil stove which is represented in the accompanying illustration. The stove, as will be seen, consists of a large reservoir provided with an opening for filling, which can be closed quite air-tight, and, if need be, opened a little by means of a screw valve. At another part of the reservoir is attached a small air-pump for creating a slight pressure upon the oil. At the foot of the burner will be noticed a small cup. To start the lamp working, this cup is filled with methylated spirit and ignited. This creates expansion, and causes pressure to act upon the oil in the reservoir, the oil thus ascending by means of a dip pipe up the central tube, where, arriving at the heated portion, it is vapourised. At the same time air is sucked in by injection action, so producing a true Bunsen oil flame. When the spirit has burnt out a few strokes of the pump are made to increase the size of the flame as may be desired. Similarly the flame may be lowered by opening the air screw attached to the filling valve, any excessive pressure being thus relieved at will. Once, however, the size of the flame is regulated, it proceeds to burn regularly with little noise and requiring little further attention. The flame has an inner strong blue cone and is quite free from smoke; it is very hot and will boil a pint of water in a remarkably short space of time. Except at the start it is free from smell. It is admirably adapted for all cooking purposes, and particularly grilling. The stove is known as the Primu No. 6, and may be obtained from Messrs. Moeller and Condrup, of 78, Fore-street, London, E.C.

THE LANCET.

LONDON: SATURDAY, MAY 29, 1897.

A REPORT issued a short time since by the Local Government Board has to do with the question of restricting attendances in elementary schools on the occurrence of diphtheria. It is compiled by Dr. SWEETING, and it shows, perhaps more clearly than any other recent document, how little is known and understood as to the circumstances under which local authorities and their officers have the right and power to intervene in matters of local school attendances for the purpose of preventing the spread of infectious disease. Diphtheria was prevalent at Gillingham to the north-east of Rochester; the population was about 31,000, and in two quarters of the year 144 cases and 51 deaths from that disease had occurred. It is not our purpose on this occasion to deal with the etiology of the disease or with its relations to Chatham and Rochester which are near by; but it seems clear that, as is so commonly the case, the spread of the disease was favoured by attendance at elementary schools, and it is interesting to note how this was dealt with, especially in the case of one school which seemed to be primarily concerned with the diffusion of the infection.

First came a verbal intimation by the medical officer of health to the chairman of the School Board to the effect that the closure of the school was necessary. The grounds on which this advice was given cannot be questioned; the advice was complied with for a period of a fortnight, and further extension of the closure was made for a third week. Then the School Board moved a resolution that the closure was "unreasonable," and what was regarded as a "vote of censure" on the medical officer of health was passed. Soon after the school was re-opened. The first stage of mismanagement which brought about the results referred to relates to the method of procedure adopted. No one can maintain that it is not proper for a medical officer of health to give advice to the parties primarily concerned with a view of checking the spread of an infectious disease, and the method adopted by the health officer in this case was probably the one which was likely to bring about the school closure in the most speedy way. It is also one that is very commonly adopted. But at the same time it is desirable for health officers to remember that such advice is in no way binding upon those to whom it is given; and, even when the advice is acted on, it is important that the matter should at once be placed on a legal footing. The law as it stands is embodied in the Education Code, and the clause in question runs as follows: "The managers must at once comply with any notice of the sanitary authority of the district in which the school is situated, or any two members thereof, acting on the advice of the medical officer of health, requiring them for a specified time, with a view to preventing the spread of disease, or any danger to health likely to arise from the condition of the school, either to close the school or to exclude any scholars from attendance, but after complying they may appeal to the department if they consider the notice to be unreasonable." Thus it will be seen that mere advice from the health officer to the school authorities is in no sense binding; indeed, it finds no place in the enactment or code: and even in cases where the health officer thinks it desirable to give such advice to the school authorities he should always proceed to advise the sanitary authority or any two of their number, in order that they, not he, should order the closure of the school for a specified time. Closure under those circumstances is binding and must be carried out, even if appeal is made to the Education Department. The actual duty and power of the medical officer of health is limited to advising his authority, and in most cases of school closure it is best that he should limit himself to it. If he does not, and the school authorities close their school on his verbal advice alone, they have no authorised certificate enabling them to claim the Government grant, notwithstanding the suspension of school operations. And not only so, but the moment the health officer begins to advise school authorities and officials, these latter come to think that they have a right to seek his advice and even to demand it in matters relating to the health of their school and even of their scholars. In fact, in this Gillingham case the School Board next went on to ask for lists of persons suffering from infectious disease, and the fact that they did not get this information had doubtless something, at least, to do with the so-called vote of censure passed on the medical officer of health, an officer with whom they had no official concern whatever. In other cases of a somewhat similar character the School Board have claimed to be advised by the health officer individually not only as to when their school or schools may be re-opened, but also as to the health of particular scholars, so that they might know whether, in the interests of the school, these scholars should or should not be allowed to resume attendance at school. All this is quite irregular; the School Boards have no more claim to the private medical advice of the medical officer of health than they have to that of any other medical practitioner. If they, for educational purposes, need such advice and counsel, they should pay for it just as any other body would do. But it is the irregular action of medical officers of health themselves which has led, in the main, to the existing unsatisfactory state of affairs; and it is most important that in the matter of school closure their advice should always be given to the sanitary authorities who, in turn, should order the school to be closed for a specified time, after which it would naturally be re-opened provided no fresh closure were enforced on the advice of the health officer.

A similar remark applies to the question of excluding children from certain houses or localities in place of entirely closing the school. School authorities often prefer closure under a certificate of the sanitary authority to the exclusion of scholars; because they think it more difficult to get the grant under the exclusion system. In one sense it is, for they so often exclude scholars on the mere verbal advice of the health officer; whereas the Education Department will take no verbal statement when the question of grant arises. In the case of exclusion the certificate of a medical practitioner is enough; but when the medical practitioner in

Hosted by Google

question is the medical officer of health it is always better that he should get the order for exclusion issued under the section we have quoted, and it can be so worded that it will serve for any house or locality in which the disease exists or may appear, thus avoiding multiple notices in case the malady extends. Much trouble has arisen from failure to comply with the precise terms of the Education Code. As a rule the simpler, but irregular, plan is adopted to please the schoolmaster or some school manager; but when these school officials find that their grant is at stake by reason of the irregular action, they do not hesitate to complain that it is the fault of the medical officer of health, and they make unreasonable demands on him for documents and for action which they have no right to claim. It may at times be inconvenient not to advise the managers directly, but if a medical officer of health feels this and does advise them he should forthwith proceed to get his advice endorsed and legalised by action through the sanitary authority.

IT may be affirmed without fear of contradiction that the value of prompt surgical intervention in acute abdominal disease can hardly be more clearly shown than in the treatment of perityphlitis, now universally admitted to depend on inflammation and ulceration of the appendix vermiformis. It has been proved in numberless instances that by such intervention peritonitis has been averted, or checked in its spread, and there can be no question that lives have been saved by this means. On the other hand, it is equally certain that lives have been sacrificed by unavoidable delay in having recourse to this radical measure. In spite of this general feeling of the necessity for resort to surgical aid, and the frequency with which it is sought, it is yet surely true that in the days before there was any idea of invoking the aid of surgery the disease was not characterised by any very great mortality. The lines of treatment were simple, and under their adoption the acute manifestations passed gradually away, in the majority of cases perhaps never to return, though in a certain proportion of cases symptoms recurred at intervals under slight provocation. It is true, however, that this fortunate result was varied by cases where peritoneal or extra-peritoneal suppurations placed life in jeopardy or were responsible for a long and weary illness that only ended in death, and there were also the cases of perforative peritonitis which hardly come under the category that we are now considering, but fatalities from which may certainly be obviated by surgical procedure.

The impunity with which the surgeon can now fearlessly lay open the abdomen, and the satisfaction felt at the discovery of a gangrenous appendix and its removal has, perhaps, rather led us to despise the *vis medicatrix* that must in past days have often effected a radical cure. It all turns on the old question whether the slow and somewhat hazardous processes of nature are not better replaced by the rapid measures of the art of surgery, the whole aim and purpose of which is to anticipate the development of greater ill, which may eventuate if the disease is left to itself. We have no intention here to discuss the indications for interference; we might even admit that the operation can be justified in every case, even the mildest. But as exhibiting the other side of the question, we would draw attention to a paper by Dr. KLEINWÄCHTER, of Breslau, a former clinical assistant of the late Professor BIERMER, who relates the experiences of the medical treatment of perityphlitis in that physician's wards in the years 1874 to 1889[1]—that is, in the pre-chirurgical days of the treatment of this affection. Dr. KLEINWÄCHTER observes that in spite of the gratitude owing to surgeons for their researches on the subject, and the striking results that often ensue from their operations, it is difficult for the physician to admit that a disease which can, in the majority of cases, resolve without the aid of surgery should come to be considered as falling exclusively into its domain. He suggests that the only way to prove the necessity for this transference is by comparative statistics, and for that reason he has collected and tabulated details of the cases in Professor BIERMER'S clinic during the period named, none of which were treated otherwise than on medical principles. These principles aim at obtaining complete rest of the intestinal canal by the strictest attention to rest of body and to diet, as well as by the administration of opium. In more detail he describes the treatment as consisting in keeping the patient absolutely at rest in bed and the relief of the pain and fever by the application of iced water compresses or an ice-bag to the abdomen, the cold being replaced by warm applications as soon as the fever subsides and signs of exudation appear. From the outset opium or morphia is administered, no matter whether there be diarrhœa or constipation. Professor BIERMER took as guides for the continuance of the opium treatment the presence of pain and tenderness and of abdominal distension, for whenever the colic recurred the patient was allowed to have another dose. Dr. KLEINWÄCHTER has known the administration of opium to have been continued for fourteen and even twenty-five days, and states that the resulting constipation was well borne, whilst other disagreeable symptoms, as hiccough, vomiting, and cough, were mostly controlled by the drug. Restriction to a fluid diet of minimal proportions is a necessity; where there is a tendency to vomit and much thirst only ice is allowed, and gradually rice-water, lemonade, diluted red wine, then thin broth, and finally milk. The opium can be omitted when pain no longer recurs and the abdominal tension does not increase, but it must be resumed on the slightest return of pain. The bowels usually begin to act spontaneously from the fourth to the ninth day, and after two or three such actions they must be assisted by enemata or mild saline aperients, as Bilin, Tarasp, or Carlsbad water. Much care is to be observed in the diet subsequently to the attack, and the patient should always be able to have recourse to a dose of opium, if at any time afterwards there is a return of colic. Should there remain any resistance in the ileo-cæcal region, due probably to adhesions or residues of exudation, it is recommended to continue the use of wet compresses and of warm baths. If the condition of the patient grow worse, the abdominal distension increase, the breathing quicken, and the pulse become more rapid, then the opium is still further pushed or replaced by morphia, the force of the heart being maintained. Professor BIERMER was careful

[1] Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie. Erster Band, Fünftes Heft. Jena: G. Fischer, 1896.

Hosted by Google

to refrain from large injections or lavage of the stomach or intestinal puncture to relieve distension.

If the foregoing be a correct account of Professor BIERMER'S practice, it will be seen to have mainly relied upon the prescription of opium, carried to an extent now rarely considered advisable, and that, too, manifestly when the case was assuming the features of general peritonitis. At the present day in most acute inflammatory abdominal diseases the free use of opium is rather deprecated, as tending to mask the symptoms and delay the intervention of surgery until all reasonable prospect of relief by this latter means is passed. It will, therefore, come as a surprise to many to learn that out of a total of 112 perityphlitic cases (3 of which relapsed) so treated in Professor BIERMER'S clinic, only 2 died—a case-mortality of 1·78 per cent. One of these fatal cases had the ordinary characteristics of perityphlitis and had progressed so far that the opium was left off, when, on the following day, after a sudden evacuation, a fatal coma supervened. The other, severe from the first, succumbed on the ninth day to diffuse peritonitis. All the rest recovered. Particulars were obtained of the after-history (up to 1889–90) of 70 of those patients who left the hospital—namely, of 61 out of 98 who left it "well" and 9 out of twelve who were discharged "relieved." Relapses had occurred in 17, or 24·3 per cent., and 2 of these were fatal. In 5 cases many recurrences had taken place, but in not a single one had the relapse supervened later than two years from the date of the primary attack.

These figures, which, it must be remembered, are culled from the practice of one hospital physician, and therefore may be taken as being based on a consistent line of treatment, are surely deserving of attention; for, although there is, even amongst the most successful operators, a commendable recognition of the fact that in the majority of cases of appendicitis resolution may occur, there is still great uncertainty as to how far it is either right or justifiable to pursue purely medical treatment. The position is one of great delicacy and difficulty; for, in contrast to these figures, we have the statistics of St. Thomas's Hospital, given by Dr. HAWKINS in his excellent monograph, which show that the general mortality from appendicitis amongst 264 cases was 14 per cent., or 26 per cent. of those terminating in abscess and 75 per cent. of those ending in general peritonitis. It is possible that had Dr. KLEINWÄCHTER been able to trace out all Professor BIERMER'S patients that the mortality from recurrence would have been found to have risen, and each such case may be reckoned as one that might have been saved by a primary operation. But then, as in many the primary attack might not have been of the severity held to justify such interference, no comparative conclusion regarding medical and surgical treatment can be drawn from them. Nor since few, if any, advocate the removal of the appendix as a routine measure do we seem to be able to institute any comparison—at least, a statistical one—between the surgical and the medical method of dealing with the disease. The claim for the treatment adopted by Professor BIERMER must then rest, not merely on its being followed by a diminished mortality, but in its favouring resolution and averting suppuration, which is, in some cases, the inevitable outcome of the lesion of the appendix. It requires more courage to act up to this belief than most of us possess now that we have become more intimately acquainted with the nature of the underlying lesion, and the possible risk entailed by delay in having recourse to surgery. Therefore, although we cannot but admire the remarkable results which we owe to the industry of Dr. KLEINWÄCHTER, we the more incline to the opinion expressed in a recent text-book[2]: "As soon as the diagnosis of appendicitis is established, indeed, pending its settlement, a competent surgeon should be associated with the physician, for the reason that in the vast majority of cases operative treatment is sooner or later demanded, while the hour for such treatment is best settled by daily conference."

A CONFERENCE was held last week at St. Martin's Town Hall, at the instance of the British Committee for the abolition of the State Regulation of Vice, for the purpose of devising measures to prevent the revival of any such regulations. It was largely attended, a considerable number of ladies being present. Mr. WALTER S. B. M'LAREN presided, Mr. JAMES STUART, M.P., being the principal speaker, and Sir JAMES STANSFELD and several ladies also taking part in the discussion. We can quite understand that the opponents of all useful and practical attempts to deal with the existing condition of things are uneasy at the great change which has of late been taking place in the state of public feeling, but we do not see how any amount of talk can alter the facts. The report of the Departmental Committee, of which the Earl of ONSLOW was the President, still remains unshaken in the contentious storm. Is there any reason to suppose that moral methods of dealing with the causes of immorality are, or need be, neglected, or that chaplains and officers (medical or otherwise) are utterly unconcerned with the moral welfare of soldiers under their charge and so neglectful of any attempt to impress on them that it is the duty of a soldier of the QUEEN to lead a good life, as was tacitly assumed to be the case by some of the speakers at the conference? How many of those who took part in the meeting have any practical acquaintance with the army or with soldiers? How many of them have really considered the history of the past and present time in regard to the subject of which they were speaking? But it is as futile to argue with people who will not face the facts as it is to attempt to stop the rising tide. Of course, Lady HENRY SOMERSET is regarded as having "given herself away," and her line of action—apparently because it was an independent one—has been emphatically repudiated. But what have they to say with regard to the influentially signed women's memorial, which expressed an earnest hope that the Government would take such steps as may be necessary to prevent the spread of disease in our army in India? The first three signatories are Princess CHRISTIAN, the Duchess of CONNAUGHT, and Princess MARY of TECK, and associated with them are many ladies of distinction, and the matrons of every large hospital in the metropolis. Miss FLORENCE NIGHTINGALE and Mrs. HUMPHRY WARD are also amongst those who have signed the document.

Hosted by Google

The women's memorial respecting the health of the army, the text of which was published in the *Times* of the 25th instant, strikes us—as it must, we think strike everyone who reads it—as a well-considered document. We applaud the courage which the signatories have exhibited in taking any part in so distasteful a subject, and we believe that their motives and reasons for doing so, as set forth in their memorial, will be gratefully recognised by all sensible people.

Lord GEORGE HAMILTON and Lord LANSDOWNE have been studiously moderate and guarded in their proposals, and in the statement of their reasons for making them; indeed, many people think that they have, on this very account, rendered the task imposed upon the Indian Government a most difficult one. It is, however, we fear, hopeless to expect that even the most fastidious regard for the moral and ethical side of the question will satisfy those whose opposition to all practical attempts to limit contagion in respect of these diseases is fanatical. We are almost tempted to ask whether it has ever occurred to some of these enthusiastic persons that they are practically bringing an indictment against the Creator for having constituted men and animals with a reproductive system, seeing the evils that are chargeable to it.

Annotations.

"Ne quid nimis."

A NEW METROPOLITAN WATER COMPANIES' BILL.

IT is true that London must wait until another Royal Commission has delivered its pronouncement upon certain subjects of controversy in connexion with the London water-supply before any definite solution of the whole question in its bearing upon municipal administration can be hoped for. But the Bill which Mr. Chaplin introduced on Tuesday last, and which was read for the first time, is a step in the right direction. Briefly, it helps the consumer so far as to enable him to secure the aid of a constituted body in the event of a grievance or unjust treatment at the hands of the water company. As matters now stand the consumer can only appeal when he finds himself in conflict with the water company to a magistrate or to the Local Government Board. In either case considerable trouble besides expense is involved, and very frequently the consumer's action is absolutely without fruit because of objections which are raised, and successfully so, as technically valid. Mr. Chaplin now proposes, pending the result of the labours of the Commission, to appoint as a tribunal in these matters the Railway and Canal Commissioners. This is rather a neat expedient, since this body is not, as it was remarked, overburdened with work, while it is clearly not desirable to create an entirely new board of reference for the purpose of giving effect to what must be only a temporary measure until the Royal Commission has drawn up its conclusions. We see in this Bill promise of the fulfilment of an undertaking, tentative though it may be, which Mr. Chaplin gave soon after the assembling of Parliament in the present session.

THE ARMY MEDICAL SERVICE.

WE would call attention to the announcement that appeared in the naval and military intelligence column of the *Times* of the 25th inst. in regard to the Army Medical Service and medical officers of the militia. The changes about to take place have an important bearing on the future of the medical service. The Army Medical Staff—and, it may be added, the army generally—are, we think, to be congratulated on the material advantages that have been gained, and on the disposition which the concessions indicate of a desire on the part of the War Office authorities to redress the grievances of which medical officers complain. It cannot be for the good of the army or the medical service that frequent changes of medical officers should take place, and that those in the administrative ranks should not remain for some time in the military districts of which they have medical charge. It may add to the difficulties of direction at headquarters, but continuity of army medical administration is most desirable on the score alike of service efficiency and individual comfort. The reduction of the length of tours on foreign service, special leave for the purpose of professional studies, and greater facilities for obtaining private leave on the part of medical officers, as well as their taking their proper position according to their army rank on all boards, committees, &c., where their presence is required, are changes so obviously right and fair that they should not stand in need of any advocacy. The announcement in the *Times* is as follows: "The continuity of army medical administration in military districts will in future be placed upon a stronger basis by the retention of surgeon-major-generals and surgeon-colonels in their staff appointments as principal medical officers until they vacate that position by promotion or retirement. The length of a tour of service in India, the Mediterranean, and Canada will in the case of officers of the Army Medical Staff be reduced from six to five years. Special leave for professional studies will be granted, and a paid substitute will also be provided for medical officers proceeding on private leave in all cases when their effective strength is below the authorised establishment. An officer of the A.M. Staff detailed to act as president or member of a mixed board, court of inquiry, or committee will take his place thereon according to his seniority as compared with that of the other members, thus clearly defining his *status* in matters unconnected with general command. The pecuniary allowance now issued to officers of militia regiments during their periods of annual training will in future be granted to medical officers when attached to these units."

NEXT MONTH.

LONDON is at present given up to the carpenters; wooden scaffolding and other signs of preparation for the coming event are already a feature that strikes the eye. We need not dwell upon the amount of good that arises from the affectionate loyalty of a people to the Queen and Royal Family. It would not be easy to form a correct estimate of it, but it is nevertheless impossible to avoid seeing that side of it which lends itself to the manifestations of benevolence and charity. The extremes of society are the rich and the poor, and they are strikingly present in a vast city like London, and it is not so much the duty as the privilege of one to help the other. It is fitting that something should be done to sweeten the memory and impart a pleasant aroma of gladness to the minds of the poorest of Her Majesty's subjects in connexion with the coming commemoration, and, thanks to the Princess of Wales's Fund, the outcast and the needy will not be forgotten on that occasion. During the sixty years that the Queen has reigned the events and changes that have taken place would fill a volume, and they have mainly been for the good and happiness of the people of this country. The greater diffusion of wealth that has taken place in those years has led to the material prosperity and comfort of the working classes and

Hosted by Google

the poor. The Queen has been young and now is old. Her life has, like those of her subjects, been one of joy and sorrow—in addition to the responsibilities appertaining to her position. The Queen has known the great bitterness of losses among those she loved, and the real loneliness of the position and sorrow of a Sovereign under such circumstances. But in the sixty years of her reign Her Majesty has shown by many acts that in joy, sorrow, or sickness she has counted upon the loyal sympathy of the people who are looking forward to next month to do her homage. It is a proud position to fill. The people of this country, whatever faults they may possess, are among the bravest, most generous, and most law-abiding people in the world, and the Queen must many times during the sixty years of her reign have been comforted by the assurance that their hopes, fears, and interests were identified with those of their ruler. It is the womanly qualities—the pity and compassion and the sympathy with all who suffer—that appeal to our people when they think of their Queen.

ICE ON BOARD OUR SHIPS OF WAR.

WE are surprised to learn from a letter in the *Times* of the 24th inst. that the vessels of our fleet are not provided with ice-making machinery. For the sick in tropical waters ice, we should have thought, was an absolute necessity. Yet it appears that it is not usual to find ice-making apparatus provided on our war-ships. If this be true, it can only be regarded as a standing reproach to the Admiralty. With all the available steam power and machinery on board these vessels, of the equipment of which we are well proud, there surely is left space enough, be it ever so small, for an ice-making apparatus. The space required would by no means be large, and the cost would certainly be very trifling, especially when compared with other machinery on board. We hope the matter will be brought to the notice of the Admiralty and that they will see their way to remove a very serious omission in the equipment of our men-of-war. It appears, however, from a letter from a firm of manufacturers in Wednesday's *Times*, that certain ships in the navy have recently been fitted up with ice-making apparatus, and that orders have been received to equip other ships of the fleet in a similar way. This is as it should be, but at the same time it indicates that not very long ago no such provision was made, so that the statements of the correspondent who first drew attention to the subject were probably right.

THE SELECTED CANDIDATES FOR THE FELLOWSHIP OF THE ROYAL SOCIETY.

OF the fifteen candidates selected by the Council of the Royal Society for election this year three are distinguished medical men—namely, Sir William Henry Broadbent, Dr. Haldane, and Dr. H. Alleyne Nicholson of the University of Aberdeen and formerly of Toronto. The work which fully qualifies these candidates in their separate fields of inquiry is well known. There is no need to dwell on the services which Sir William Broadbent has rendered to medicine—they are well known to our readers—while only recently Dr. Haldane, as will be very generally remembered, has added considerably to his credentials by his recent and most able report to the Home Secretary on the Causes of Death in Colliery Explosions. In addition to medicine, Dr. Nicholson represents also natural history and palæontology, of which subjects he is a distinguished student. Chemistry is somewhat fully represented by three candidates; of these, perhaps, the name of Dr. Kipping is most widely known amongst chemists as a distinguished worker in the field of original inquiry. He has contributed a very valuable series of papers bearing chiefly upon the synthetical formation of organic compounds. Mr. John Millar Thomson is the popular secretary of the Chemical Society and professor of chemistry at King's College. He has written some interesting papers on the phenomena of solution and crystallisation. Mr. Francis Henry Neville has been engaged chiefly in the teaching of natural science at Sidney Sussex, Cambridge. He was fifteenth wrangler in 1871. His work has been directed chiefly to the composition and behaviour of alloys. Geology is represented ably by Dr. Robert Bell, the assistant director of the Geological Survey of Canada. Dr. Bell has published an enormous amount of work based chiefly upon the geological and topographical exploration of a large tract north of Lake Huron. Dr. Charles Chree is the superintendent of Kew Conservatory; he is the author of several mathematical papers, contributed to various scientific societies, on heat, magnetism, and stress. Ornithology is represented by Mr. Henry John Elwes, who was president of the Entomological Society two years ago, and at an earlier date vice-president of the Horticultural Society. It is pleasing to see that our colonies will be represented at the Royal Society in the branch of zoology and comparative anatomy by Dr. William A. Haswell of the University of Sydney. Zoology is again represented in the person of Mr. George Bond Howes, assistant professor in the Royal College of Science. His connexion with literary work will be remembered in the "Atlas of Elementary Biology," and the enlarged edition of "Huxley and Martin's Practical Biology." He has also done some valuable original work. Mathematics is represented by Mr. George Ballard Mathews, professor of mathematics in the University College of North Wales; Botany by Mr. George Robert Milne Murray, of the British Museum; astronomy by Mr. Herbert Hall Turner, the Savilian professor of astronomy, Oxford, while natural philosophy has found an able representative from the University of Dublin in the person of Dr. Frederick Thomas Trouton, who has contributed a number of papers on various physical subjects to the *Philosophical Magazine* and to *Nature*, and many of them are published in the transactions of various learned societies.

THE ABUSE OF DISPENSARIES IN NEW YORK CITY.

FOR some time past there has been much dissatisfaction existing amongst the medical men of New York city with regard to the abuses said to be prevalent in the management of its charitable dispensaries. The subject has been thoroughly looked into and discussed, and it appears after this threshing-out process to have been proved most conclusively that charity has been imposed upon in a wholesale manner. At meetings of the Medical Society of the county of New York several medical officers of dispensaries gave evidence testifying to the shameless way in which persons who were well able to afford a substantial fee obtained advice under the plea of poverty. Instances were given of persons driving to a dispensary in a carriage to seek relief. In one case when the medical man advised the patient to be much in the fresh air and suggested trips on the ferry-boats as a cheap mode of attaining that object, he was somewhat taken aback by the invalid asking whether a voyage to Europe would not answer the purpose equally well. It was, in fact, clearly shown that these charities were extensively used by a class for whose benefit they were most certainly not intended. The New York Medical Society for advancing the Practice of Medicine, representing the sentiments and wishes of the majority of the medical practitioners in New York City, has introduced a Bill into the State Legislature to regulate dispensary relief in that city and to protect the interests of the private practitioner. By Section 5 of this Bill "all persons wishing to be treated at a dispensary shall be compelled to produce to the persons

Hosted by Google

carrying on said dispensary a certificate from the owners of the premises wherein such persons reside, or from the police captain or person in charge of the police in the district in which he or she resides, or from the alderman of the district, or from any charity organisation, that the said applicant is a poor person and unable to pay for medical treatment." Section 6 states "that any person applying to a dispensary to be treated and not fulfilling these provisions, or any person aiding anyone so applying to be treated or signing such certificate knowing that such a person so applying is not a poor person, shall be guilty of a misdemeanour." "The Bill if passed will also do away with any kind of payment, as one of its provisions stipulates that all persons who can show themselves to be entitled to treatment shall receive that treatment free in addition to being supplied with medicine and appliances, and further provides that no one conducting a dispensary shall receive any pay whatever." The last section of this Act reads that "the husband and wife shall be jointly and severally liable to pay for professional services of a physician rendered to them, or either of them, or any member of their family, and the joint or several property of the husband and wife shall be liable to levy and sale under an execution upon such judgment, except such property as may by law be exempt from levy and sale under an execution." This clause is of great importance to the medical profession in New York, for as the law stands now a man can evade the payment of his just debts by having his property made over to his wife. The principal medical societies of New York city are given the power each to appoint one person to form a board for the purpose of supervising the conduct of dispensaries, and it is proposed that any person or persons violating this law shall be liable to a large fine or six months' imprisonment. The *New York Medical Journal* criticises the Bill as crude and exacting in its requirements and faulty in its form.

SECONDARY RASHES IN SCARLET FEVER.

SECONDARY rashes during the convalescent stage of scarlet fever, though not very uncommon, are unnoticed by most writers. They must not be confounded with true relapse. Some time ago we published an article by Mr. Manning entitled, "The Skin Eruptions which occur in Septicæmia following Scarlet Fever and Diphtheria."[1] In 2·1 per cent. of nearly 6000 cases of scarlet fever and diphtheria under his care in the City Hospital, Birmingham, he found a condition to supervene characterised by wasting, pyrexia, a peculiar erythematous eruption, and high mortality. It usually supervened in the second week of the attack of scarlet fever, and was almost invariably attended with sloughing in the throat. He therefore attributes it to septic poisoning from this source. Dr. J. O. Symes[2] has recently described a secondary rash, observed in a series of cases of scarlet fever in the London Fever Hospital, apparently of a different nature. The eruption appeared about the third week, almost invariably in patients in whom the throat symptoms had been severe, and frequently coincided with a recrudescence of tonsillitis. Its character varied in different cases, being either erythematous, urticarial, eczematous, papular, or hæmorrhagic. It does not appear to have been caused by septic absorption from the throat, because tonsillitis was absent in some cases, in others it preceded the eruption, and in none was there ulceration or sloughing. Complications such as diarrhœa, vomiting, and nephritis sometimes occurred, which leads the writer to suggest that all the symptoms may be due to a critical elimination of the disease products in the third week. Mahomed observed certain changes between the eighteenth and twenty-second day—a rise of arterial tension, a diminished excretion of urine, pyrexia, albuminuria, otorrhœa, adenitis, and diarrhœa; but he does not mention secondary rashes. As an indication of these complications the detection of the rash is important. The writer states that similar eruptions are frequently seen in scarlatinal "rheumatism," but that it was only present in two out of the nine cases. This suggests to us the conclusion that the eruption and other symptoms are of the same nature as the "rheumatism" and due to a common cause which produces varying effects.

MILK AND TUBERCULOSIS.

ALMOST day by day fresh evidence accrues of the extreme necessity of placing cows under the best possible sanitary environment, since darkness, filth, and defective ventilation are favourable conditions for the development of tuberculosis, and the milk of tuberculous cows, especially when the disease affects the udder, is an undoubted source of infection. In a recently published report on tuberculosis as affecting the milk supply of the city of Liverpool the medical officer of health, Dr. Hope, states that the investigation of the bacteriologists showed that 2·8 per cent. of the samples of milk taken from the city shippons contained the tubercle bacillus. As he points out, and as we emphasised only last week, this doubles the need for strictly applying the by-laws. Dr. Hope very properly observes that, important as this result is, it sinks into insignificance compared with the large proportion of milk infected with tubercle which is sent in from the country, this proportion amounting to no less than 29·1 per cent. In the same way what guarantee, we may ask, have we that milk imported in a frozen state from foreign countries is free from infection?

THE MANCHESTER SEWAGE PROBLEM.

WE have received from Mr. Bradley, a member of the Manchester City Council, a paper read before the Manchester Statistical Society, entitled "Manchester Sewage Problem, with Suggestions for its Solution and Suggested Amendments of the Rivers Pollution Prevention Act." The great difficulty is so to deal with the immense volume of 26,000,000 gallons of sewage per day, that the sewage effluent shall be pure enough to be discharged into "a nearly stagnant portion of the Ship Canal." The question of filtration through land is thus dismissed as impracticable:—"First, because we cannot obtain the necessary quantity of land, and, secondly, if we could the land would be of a kind that would be unworkable and probably a source of infection to the whole neighbourhood." He then considers the methods of chemical precipitation and subsequent treatment by artificial filters. "At Davyhulme the precipitation is effected by the addition of milk of lime, and subsequently by the addition of copperas (protosulphate of iron), about seven grains of each being added to every gallon of sewage." As a rule the effluent does not come up to the standard of the joint committee, which, by the way, comes in for some of Mr. Bradley's severest strictures. He says it "apparently exists only to harass and command." This standard, which Mr. Bradley considers unreasonable for Manchester, is that any effluent entering the canal shall not absorb in four hours more than one grain of oxygen in a gallon, and that it shall not contain more than 0·1 of a grain of albuminoid ammonia per gallon, or by weight one-tenth of a grain of albuminoid ammonia in 70,000 grains of effluent. Such an effluent can be produced at Manchester, but at such a cost, and requiring such constant supervision that Mr. Bradley considers it impracticable. Nor does he hope much from invoking bacterial energy. He advocates the discharge of the sewage by a culvert carried to Randall sluices below Warrington, in the estuary of the Mersey, where what he now calls the "effluent water" can be discharged directly into the receding tide. In

Hosted by Google

order to supply the canal with an equivalent for the 26,000,000 gallons of sewage effluent sent down the culvert he would provide a pumping station at Latchford to raise any required quantity of water from the tidal level to the higher level above the locks. If the pumping station or an "occasional discharge of the Manchester effluent water into the canal" were considered objectionable he would flush the docks at Pomona with 10,000,000 gallons of Thirlmere water. Mr. Bradley is really advocating the plan proposed by the Rivers Committee and emanating from the City Surveyor. It is a confession of failure over which Mr. Bradley becomes rather eloquent. "When they had the culvert they would be done with the difficulty, they would not be constantly harassed by law, they would be perfectly free, and it would be as grand a thing for Manchester" (to pour their filthy effluent into the estuary of the Mersey) "as was the bringing of pure water from Thirlmere." He evidently looks with regret on the loss of the ancient privilege of pollution, and speaking of the river, says: "It is the same stream that has for centuries conveyed the drainage of Manchester to the sea, and it is especially unreasonable on the part of the majority of the Mersey and Irwell Committee to oppose in Parliament and prevent one of the most important trading centres in the world from exercising her ancient privileges." He would do away with the present Mersey and Irwell Committee, and proposes "a new form of board constituted more in accordance with the requirements of Manchester."

CEREBELLAR FUNCTIONS.

IN a recent number of the Proceedings of the Royal Society a preliminary account appears of some interesting experiments by Dr. Max Löwenthal and Mr. Victor Horsley on the relations between the cerebellar and other centres, especially with reference to the action of antagonistic muscles. These experiments were undertaken because of an observation that when both cerebral hemispheres were removed, and as a result active extension tonus of the limbs was obtained; faradaic excitation of the upper surface of the cerebellum caused immediate relaxation of such tonus so long as the current was applied, but as soon as the latter was shut off the tonus was immediately re-established. Such an observation, indicating, as it did, a distinct connexion between the cerebellum and the lower centres, made careful examination necessary, and it was found that such an effect was constant provided the tonus was well established, and the effect was not merely an actual relaxation of the triceps, but also a marked contraction of the biceps. Experiments were arranged in which the effect could be graphically recorded, and in the dog and cat it was found that excitation of the left motor cortex and of the left corona radiata produced invariably symmetrical and synchronous contraction of the prepared muscles, biceps and triceps of the right side. Excitation of the crusta on the cut surface before the general tonus was established produced invariably contraction of both biceps and triceps; excitation after it was established, of the left crusta produced in thirteen cases contraction of the biceps and contraction of the triceps, in two contraction of the biceps and relaxation of the triceps, and in one relaxation of the biceps and contraction of the triceps. Excitation of the cerebellum produced very constant effects. After the tonus established by removal of the cerebellar hemispheres was present excitation of the cerebellum caused a striking and active relaxation of the triceps and an active contraction of the biceps on the same side as that stimulated. In twenty-nine experiments it was found that the muscles of the right arm could be influenced by excitation of both halves of the cerebellum, but the effect was greater on the same side as that stimulated. In five experiments excitation of the left half of the cerebellum evoked relaxation of the biceps on the opposite side. When the tonus produced by removing the cerebral hemispheres was not yet established excitation of the surface of the cerebellum constantly produced atonic contraction of either the triceps or biceps, or of both together. Synchronous excitation of the cerebral area for the forelimb and of the cerebellar focus produced, in cases in which the cerebellum is definitely excitable, an addition to the tonus previously elicited from the cortex cerebri. The inquiry is very interesting, and seems likely to throw light upon some of the functions of the cerebellum hitherto so obscure.

OXFORD GRADUATES' MEDICAL CLUB.

THE summer dinner of this club was held at Limmer's Hotel on May 20th, Dr. Whipham being in the chair. About a hundred members and guests were present, among the latter being Dr. Wilks and Mr. Clinton Dent. The toasts, which, according to the unwritten law of the club, were as few as possible in number and proposed in the fewest possible words, were given by Dr. Whipham, and consisted of "The Queen" and "The Club and its Guests." In proposing the latter Dr. Whipham referred to the losses the club had sustained by the deaths of Mr. George Child, of Oxford, and Dr. James Andrew.

THE DANGERS OF CELLULOID.

WE drew attention last week to the extreme inflammability of the substance called celluloid, and we pointed out that though the celluloid films of the kinematograph employed on the occasion of a demonstration at the Bazaar in Paris, where such an awful disaster happened, might not have been the primary cause of the fire yet doubtless the presence of long sheets of this highly inflammable material accentuated the rapidity and fierceness of the conflagration. Could nothing be done, we urged, to make celluloid less inflammable without impairing its transparency. We believe that by interposing a bath of alum solution between the source of light and the pictures a great proportion of the heat rays would be filtered out so that little heat would be concentrated upon the inflammable screen. The danger is no imaginary one, and all such public demonstrations should, we consider, be subjected to rigid inspection and control. Another fire at Paris was reported in the papers on Tuesday last arising from the probably careless handling of a kinematograph. It so happened that there were only thirty spectators present, which considerably lessened the chance of a serious panic. The kinematograph as a source of amusement and, we may add, of instruction is being very largely employed in crowded places of public resort, and it is imperative, we think, that some action should be taken to provide as far as possible for the safest possible conditions of carrying out this kind of entertainment.

THE BECKENHAM AND PENGE MEDICAL SOCIETY: THE BATTLE OF THE CLUBS.

A VERY useful and sensible discussion followed the annual dinner of the United Beckenham and Penge Medical Society, at which Mr. Frank Sturges presided. The health of the society was proposed by the Rev. Charles Green, vicar of St. Paul's, Beckenham, in a speech which showed great appreciation of the profession and the value of local medical societies in promoting good fellowship and professional harmony. He alluded to what seems to have been a somewhat warm newspaper discussion on medical clubs and the objections of the profession to unfit persons as members. He rightly observed that mere temper would not solve such questions, unless, indeed, it is that

Hosted by Google

good temper which comes of a good cause and a generous disposition to be reasonably accommodating to those who need our services. Mr. Sturges, in his reply, stoutly maintained the duty of the medical profession to defend itself against a small minority who are ready to accept any terms in medical aid associations, even in those which work by paid canvassers canvassing the patients of private practitioners. A gentleman had lately been imported from such an association to the neighbourhood full of sympathy with clubs in their wrongs at the hands of a cruel-hearted profession, and willing to accept all their appointments on their own terms. This was most unsatisfactory just when the principal clubs of the district had come to terms with a very united profession. Mr. Sturges sees the difficulty of legislation in this matter and suggests that Universities and qualifying bodies should insert a clause in their degrees or diplomas under which no one could accept an appointment which in the opinion of the profession is derogatory without risk of losing his degree or diploma. Already most of the qualifying bodies —not universities—have power to censure or punish behaviour or methods of practice inconsistent with the dignity of the profession. They need to be stimulated to action by such societies as that of Beckenham and Penge. Meantime the public opinion of the district must find expression—dignified and calm, as Mr. Green suggested, but clear and decided, as Mr. Sturges, representing thirty-five medical men, exemplified.

PULMONARY TUBERCULOSIS AND ATMOSPHERIC IMPURITY.

THERE has just been issued by Dr. A. K. Chalmers, the medical officer of health of Glasgow, a report upon the distribution of turberculous diseases in that city. Glasgow, with its wide area, its numerous sanitary districts, and excellent sanitary organisation, is just the place for an inquiry of this kind, since the various districts exhibit marked contrasts in respect to density of population, social status of their inhabitants, and in the class of dwellings. Dr. Chalmers deals with all forms of tuberculous disease, grouping its varieties in the categories of pulmonary phthisis, tabes mesenterica, tuberculous meningitis, and "other forms," including "scrofula." He shows that the mortality from all these affections has very markedly diminished of late years, the average annual death-rate per million living having been for phthisis 2849 in 1883-88, and 2318 in 1889-94, a reduction of 18·6 per cent. Similarly there has been a fall in the death-rates from all the other forms of tuberculous disease, amounting in the aggregate to 18·7 per cent., the reduction being most marked in the class of tabes mesenterica and least in that of meningitis. The main part of his report, however, deals with the incidence of fatal cases of pulmonary tuberculosis in the various districts, in comparison with the liability of the communities to the inhalation of atmospheric air rendered impure by respiratory exhalations. He arrives at this approximately by determining, not only the population density of each district, but also what he terms the "room density"—that is, the average number of persons per room in the houses of the district. This calculation cannot, of course, take account of the actual cubic space of the dwellings, or of the greater or less facilities for ventilation; but neglecting these and other modifying circumstances it yet comes out very clearly that the amount of phthisis does vary proportionately to the room-density. This is well shown by his conclusions, which we cannot do better than quote. They are:—

1. The room-density of the whole city fell from 2·040 in 1881 to 2·033 in 1891, or a decrease of 7 persons per 1000 rooms, and its phthisis-rate from 268 to 230 per 100,000 living.

2. All districts, save one, having a phthisis death-rate above the mean have a room-density also above the mean. St. Enoch-square district is the only exception to this.

3. In all these districts, save St. Andrew's-square, the room-density was greater in 1881 than in 1891.

4. Eleven districts have a phthisis death-rate below the mean; five of them have a room-density in excess of the mean, which is tending toward increase in three of them.

5. These exceptions are sufficiently large to show that the relationship between room-density and phthisis is not a simple one, and that excessive density is not at once responded to by an increased phthisis-rate; but in nine districts where the room-density increased between 1881 and 1891 the phthisis death-rate fell 13·5 per cent., whereas in fourteen districts where the room-density was reduced the phthisis-rate fell 16 per cent.

Thus, as Dr. Chalmers says, the death-rate from phthisis is decreasing more rapidly in those districts which have a concurrent decrease in room-density. His report is amply furnished with statistical information that bears out the conclusions at which he has arrived. The practical lesson is of the greatest importance. It is that which we fear is never considered in the building of great towns, where the tendency is to encroach upon air-space, and if not to cause an increase in the actual density of the population, to at any rate diminish the opportunities for that thorough permeation of pure air in and around dwellings which is the main element in all the prophylaxis of pulmonary tuberculosis.

THE ALDERSGATE-STREET EXPLOSION.

THE evidence adduced at the inquest held upon the body of Henry Pitts, who lost his life in the mysterious explosion on the underground railway on April 26th, confirms unfortunately the views which we expressed in our issue of May 1st in regard to the origin of this occurrence. We feared then that everything tended to show that a dastardly and cowardly miscreant was at large amongst us, and that he had employed a powerful explosive, adjusted to explode at a certain time, for his hellish and insane purpose. The same conclusion has been arrived at by Sir Vivian Majendie, Her Majesty's Inspector of Explosives. At the inquest he said that "he had no doubt in his mind that the explosion was due to a high explosive, which had exploded on the floor of the carriage, and which high explosive was not contained in a metal case, but was fitted with a fuse and put into the train." Further evidence given by railway officials appeared to distinctly confirm this view. Sir Vivian Majendie remarked that this was the fourth explosion on the underground railway, and all that remained was to find the perpetrator of the outrage. The only consolation to be derived from the issue of the occurrence is that not more lives than one were lost, and considerable praise is due to that engine-driver who, as soon as he was aware of what had happened, turned on his whistle, and so warned other trains not to enter the station. In the confusion that prevailed the results of a train entering upon the scene of the explosion at that moment might have been disastrous indeed.

ENLARGEMENT OF FUNCTIONS OF THE METROPOLITAN ASYLUMS BOARD.

No student of disease, or even of sociology, can fail to watch the work of the Metropolitan Asylums Board. There is not much new to report in respect of its ordinary work in the fortnight ending on May 20th. The cases notified to the Board and the cases admitted were both a little more numerous than in the preceding fortnight. Of the 1429 cases notified to the Board, as against 1341 in the preceding fortnight, 749 were received into the hospitals of the Board. The meeting had unusual interest on two grounds. First, the presentation of the annual report by the chairman; and,

Hosted by Google

secondly, the adoption of a report of a special committee on steps necessary for accommodating certain classes of diseased pauper children. The most important part of the chairman's statement was that for six months of the year the managers had to refuse admissions, which would have filled 500 more beds than they had. At one time, with a normal accommodation for 3900, they had 4996 cases, or an excess of nearly 1100 cases. The expenditure meantime proceeds by leaps and bounds, the liabilities on loans on Sept. 30th last being £1,741,991, as against £1,563,844 at Michaelmas, 1895. No attention seems to be given either by the Board or by the Local Government Board to the question how far this ever-enlarging expenditure might be met by excluding unfit cases or cases which might be treated at home. It is noticeable that of the 3400 servants in the employment of the managers when the Poor-law Officers Superannuation Act passed (1896) 2444, or more than two-thirds, declined to take advantage of its provisions. The Board, undaunted by its present responsibilities, adopted a report formulating plans for the accommodation of 800 cases of contagious ophthalmia, 400 cases of ringworm of the scalp, besides accommodation for weak-minded and physically infirm children who cannot well be trained in ordinary schools, and for remand cases under the Industrial Schools Act. It will be interesting to see how far an essentially medical treatment of such classes of unfortunate children will tend to eradicate the physical taints of pauperism and to place them on a fairer level of health for the race of life. We have great faith in the far-reaching effects of a sound medical treatment, not restricted by the considerations that too often weigh with guardians.

PUBLIC VACCINATORS AND THE SUPERANNUATION ACT.

WE have on previous occasions[1] drawn attention to the absence of any provisions being made in the Poor-law Superannuation Act for public vaccinators, an omission which was due to the fact that they did not look after their own interests when the Act was being framed in the same manner as the clerks to guardians did, who stand, as regards their offices of registrars of births and deaths, exactly in the same position as district medical officers do as regards their posts of public vaccinators. The Poor-law Medical Officers Association has very properly been considering the matter, and submitted a series of questions to Sir Robert Reid as to the construction of the new Act—namely, if public vaccinators can be regarded as coming within the scope of the Act, whether they hold no other post under the Poor-law or that of district medical officer in addition. His opinion on all these questions is virtually that a public vaccinator, whether he holds the post of district medical officer or not, is not, in his capacity of public vaccinator, *an officer* employed by the guardians, and therefore cannot count the vaccination fees as part of the emoluments on which a pension can be based. To the uninitiated and to the unlegal mind these quibbles seem very curious, but Sir Robert Reid's opinion only confirms that of the Local Government Board, and, therefore, the only thing that remains is to test the matter in one of the courts. But in all probability the money so expended would be better devoted to getting an alteration of the law. The nurses have also been rather hardly dealt with in the Superannuation Act, and from much the same reasons. Why should not the public vaccinators coöperate with the nurses? The latter have been promised some valuable help to obtain a short amending Act this session, which will enable them to have the option of excluding themselves from the provisions of the Act if they choose. It would be only fair if a clause could also be inserted in the proposed amending Act setting forth in the wording of Section 19 of the Act of 1896 a provision that "for purposes of this Act" public vaccinators "are deemed to be in the service of the guardians of the union or parish" with whom they have a contract for the performance of vaccinations. Many things in this world may be done by coöperation which cannot be done single-handed, and we commend the idea to the notice of the public vaccinators, who certainly have grounds for feeling aggrieved at their exclusion. The Workhouse Infirmary Nursing Association (6, Adam-street, Strand), always mindful of the interests of Poor-law nurses, could doubtless give information as to how matters now stand as regards the proposed amending Act; or perhaps Mr. Rutherglen, the clerk to the guardians of Kensington, who took an active part in promoting the existing statute, would aid the public vaccinators in getting their disabilities removed.

THE JENNER MEMORIAL MEDAL OF THE EPIDEMIOLOGICAL SOCIETY.

THE support which the profession has given to the Jenner Memorial Medal Fund has, we are glad to hear, enabled the Epidemiological Society to found a medal, and at the annual meeting of the society which was recently held it was announced that the design and execution of the medal had been entrusted to Mr. Allan Wyon, F.S.A. On the obverse of the medal is to be the head of Edward Jenner, while on the reverse is a representation of the globe similar to that shown on the diploma of the society. It was announced at the same meeting that Lord Lister had accepted the office of Honorary Vice-President, also that the society had determined to published in pamphlet form the extremely able paper in which Dr. McVail dealt with the Dissentients' Statement in the report of the Royal Commission on Vaccination.

VESTRIES AND QUACK ADVERTISEMENTS.

A CORRESPONDENT writes: "I should like to call your attention to the following circumstance: I think that your opinion about it will coincide with mine, and you may be able to get the abuse removed, or suggest a means for doing so. In the handsome and commodious new public urinal in Hyde Park, close to the Marble Arch, there is a clock in a conspicuous position disfigured by an advertisement in large letters round its face of Beecham's Pills, &c., and round the pendulum below is added 'Sale 7 (or some such number) every second.' The Vestry of St. George, Hanover-square, is, of course, responsible for this monstrosity. I drew the attention of a member of the Vestry to the matter some time ago, and he promised to bring the matter before the Vestry; but I observe that nothing whatever has been done." Now a urinal may be a very good place in which to advertis quack medicines, and it is, in fact, a place often used by the bill-posters of persons who may be termed irregular practitioners; but the bill-poster and the vestry of St. George, Hanover-square, stand in somewhat different relations towards the public. Indeed, we believe that some vestries propose to prosecute the bill-stickers for a proceeding similar to that of which the vestry of St. George, Hanover-square, has been guilty. For a vestry itself to advertise in this extremely conspicuous manner a quack remedy is, to put it mildly, an indiscretion. To us, moreover, viewed from a commercial aspect, it would seem to be an extremely bad stroke of business unless the vestry obtained from the proprietors a great deal more than a clock. Suppose we estimate the value of the clock, for argument's sake, at £50, the annual value of £50 is not more than £2, and in the case of a clock would decrease with the

Hosted by Google

wear and tear of time. The annual value to the proprietors of these pills of a permanent advertisement in a public place with sitting and standing accommodation during the long hours that it is open for many hundred persons would, at the ordinary scale of English advertisements, be many hundred times £50.

THE BLACKWALL TUNNEL.

THE new tunnel under the Thames, which was opened on May 22nd, must prove of immense value to the inhabitants of the East-end of London, who hitherto have had no free river crossing between London-bridge and Woolwich. Great praise is due to the London County Council for having successfully carried the work through, and as Lord Rosebery humorously remarked at the dinner given in celebration of the opening of the tunnel, "if a political Cromwell from one or other of the Governments which succeed each other in Downing-street should step forward and say: 'Remove that bauble' (the London County Council) and sweep them out of existence, they would always live, if only by the memory of the Blackwall Tunnel." From an engineering point of view the work must rank among the more remarkable triumphs of the Victorian era, and from a medical point of view it must also be regarded as a remarkable performance. In all great building works there are generally a number of serious accidents, and in the present instance the probability of an increase in the proportion of casualties was enhanced as the men had to work in compressed air, which is now generally used in excavations beneath water. Notwithstanding the fact that the tunnel has taken five years to complete, Dr. Collins was able to inform His Royal Highness that the operations had been carried out with unusual freedom from serious accidents—a fact which speaks volumes for the great care which had been taken to protect the operatives.

THE IODINE TEST FOR SEMEN.

THE difficulty of identifying spermatozoa by the microscope in the case of old stains is admitted. Florence of Lyons has introduced a chemical test which appears to be valuable,[1] judging by recent reports. The reagent is one used in testing alkaloids, known as the tri-iodide of potassium (KI_3). The formula is: iodide of potassium, 1·65 grammes; iodine, 2·54 grammes; and distilled water, 30 c.c. When a drop of the liquid obtained by moistening a seminal stain is placed side by side with a drop of this solution on a slide large numbers of peculiar brownish red, pointed crystals appear. They are rhomboidal and closely resemble hæmin crystals. Dr. Wyatt Johnson states[2] that he readily obtained the reaction with stains a year old. He also confirms Florence's statement that other secretions of the body, such as blood, urine, sweat, saliva, tears, bile, milk, pus, nasal or vaginal mucus, will not give the reaction. With the semen of animals in some cases he obtained a doubtful reaction. Dr. W. F. Whitney[3] also obtained the reaction readily. But as alkaloids give a precipitate with the reagent, its value, like the guaiacum test for blood, is chiefly negative. The last writer has found the following method of examining a seminal stain even as old as two and a half years successful. A drop of fluid obtained from the moistened stain is evaporated and fixed by a flame. The film is stained with eosin and methyl green and mounted. At the base of the head of the spermatozoa is a hemispherical portion which stains a deep green, whilst the anterior part and tail stain red. This serves at once to identify them, as there is no other oval spore or cell which has an eccentric hemispherical nucleus. He furthermore claims that the test proves them to be human, as in no other animal is there a deep staining. When this test is combined with Florence's there ought to be no difficulty in coming to a conclusion.

THE SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of this society was held on Wednesday, May 19th, at 5 P.M., Sir James Paget, President, being in the chair. From the report read by the secretary it appeared that thirteen new members had been elected in 1896, thirteen had died, and four had resigned, leaving 292 on the books. Four widows and four orphans had been added to those already in receipt of grants, four widows had died or become ineligible, and one orphan had ceased through age to be eligible for further assistance, and fifty-three widows and eleven orphans had received £2893 10*s.* during the year. The total receipts available for the payment of grants and expenses had been £3291 11*s.* 5*d.*, and the grants and expenses had amounted to £3136 13*s.* 9*d.*, leaving a balance of £154 17*s.* 8*d.* The funded property of the society, now £97,300, had been increased by the investment of the residue of Miss Emma Carpue's legacy of £1600. A vote of thanks to the editors of the medical journals for their kind assistance in making known the work and objects of the society was proposed by Dr. Wilks, seconded by Mr. Milburn, and carried unanimously. A special grant of £26 was made to a widow. Dr. Wilks, Dr. Pollock, and Mr. Felce were elected vice-presidents, Dr. Brodie, Dr. Ogle, Dr. Blandford, Dr. Slight, Dr. de Havilland Hall, Dr. James Miller, Mr. Lovett, and Mr. Day were elected directors to fill the vacancies in the list of officers for 1897–98 caused by death and the retirement of the six senior directors. The acting treasurer, Dr. Potter, proposed a vote of thanks to the President, Sir James Paget, for presiding at the meeting. The vote was passed with great cordiality.

THE first annual meeting of the National Association for Promoting the Welfare of the Feeble-minded (secretary, Miss Paul; temporary office, 27, Percy-street, W.) will be held at 36, Lancaster-gate, W., on June 2nd, at 4 P.M. Dr. Savage, Dr. Frederick Needham, and Mr. G. T. Pilcher, of the Charity Organisation Society, are announced to speak.

WE have received the report of the medical superintendents upon the use of antitoxin serum in the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board during the year 1896. The report is an exhaustive statistical study of its subject, an analysis of which we shall place before our readers next week.

H.R.H. PRINCESS HENRY OF BATTENBERG has fixed Saturday, July 31st, as the date for the ceremony of laying the foundation stone of the eleventh block of houses of the Royal National Hospital for Consumption, Ventnor, to increase the accommodation to 155 beds.

H.R.H. PRINCESS LOUISE, Marchioness of Lorne, has graciously promised to open, some time in July, the Convalescent Home at Cranbrook, Kent, given by Mr. Passmore Edwards to the Metropolitan Hospital.

FIELD-MARSHAL SIR JOHN LINTORN SIMMONS, G.C.B., G.C.M.G., will distribute the prizes to the students of Charing-cross Hospital on Wednesday, June 2nd, 1897, at 4 o'clock precisely.

GUY'S HOSPITAL has received £1000 from Mr. Charles Gassiot towards the cost of building a nursing home in connexion with the hospital.

Pharmacology and Therapeutics.

RADIANT HEAT IN ULCERS OF THE LEG.

DR. COLLEVILLE, professor of Internal Pathology in the Rheims School of Medicine, treats ulcers of the leg by exposure to heat in a simple way without any very elaborate apparatus. All that is required is a square plate of metal which will stand heating and a Bunsen burner. The blue flame of the latter impinges on the metal so as to bring it to a dull red heat, and the ulcer is exposed to the action of this at a distance of about ten inches, the rest of the limb being protected by bandages. The temperature is about 45° C. which is easily borne, and the flame is regulated so as to maintain this temperature at the wound during the whole of the sitting which lasts for from twenty minutes to an hour. At the conclusion the surface is found to be glazed over, large granulations being visible through the semi-transparent coating. It is best to leave the ulcer exposed to the air for some time, and when it is dressed care should be taken that its surface is not touched by the aseptic gauze or other material used. Some improvement is generally experienced by the patient even after the first sitting, and cicatrisation is completed in from five to twenty-five applications. In the later sittings, when the ulcer is nearly healed, a more moderate degree of heat may be employed. Where gas is not available the heat of the sun or that of a fire may be utilised. Dr. Colleville attributes the beneficial effect of this method to the combined action of heat, light, and ventilation.

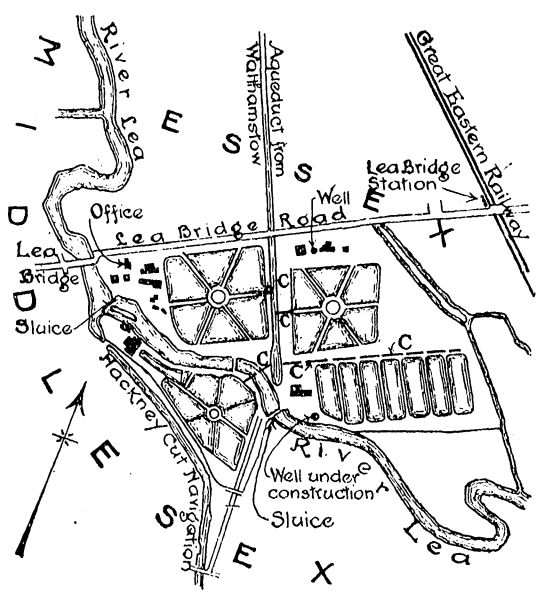
PARALYSIS FROM THE MEDICINAL ADMINISTRATION OF ARSENIC.

In a recent number of the *Glasgow Medical Journal* Dr. Middleton has published an interesting case of a boy, aged eleven years, who, on account of a skin affection, had Fowler's solution of arsenic administered to him in increasing doses. The administration was commenced in January and the first symptoms of paralysis appeared in March. Examination in the following June revealed complete flaccid paralysis in all four extremities, with atrophy and loss of knee-jerks. There was considerable pain on pressure of the muscles and nerves, but no obvious impairment of sensibility.

OIL OF WINTERGREEN AS AN EXTERNAL APPLICATION IN RHEUMATISM.

According to M. Lemoine local applications of oil of wintergreen are valuable in rheumatic fever, acting more rapidly in relieving pain than salicylate of soda and being free from the liability to produce tinnitus or giddiness, which sometimes follow the use of the latter drug. He soaks a piece of lint in two or three drachms of the essential oil, and applies it to the skin; the whole is then completely covered by oiled silk, which well overlaps the lint, and carefully bandaged so as to prevent external evaporation. The application is made over the painful spot if this is conveniently situated. If otherwise the thigh or arm is chosen. In this case the oiled silk should be long enough to encircle the limb, and the absorption of the salicylate of methyl which forms some forty per cent. of the oil produces almost as good a result as if applied to the seat of the pain. This method of treatment answers very well also in some cases of sciatica and, according to M. Siredey, in chronic rheumatic affections, where it may be used for a considerable time without any ill effects, either local or general. Here it acts better when applied directly to the affected joints than when the dressing is placed round the shaft of the bone. The strong smell of the oil is the only inconvenience. The same application has proved useful in relieving the lightning pains in a case of locomotor ataxy. The use of oil of wintergreen as an external application in chronic and subacute rheumatism is of course not anything novel, though the particular method of its employment may perhaps be so. Mr. J. D. Staple, however, used it in the Stockport Infirmary several years ago as a liniment combined with an equal quantity of olive oil, and reported[1] that in only two out of a hundred cases of chronic rheumatism did it fail to relieve the pain.

[1] THE LANCET, Aug. 30th, 1890, p. 444.



The Lancet Special Commission ON THE METROPOLITAN WATER-SUPPLY.

XIV.[1]

EAST LONDON WATERWORKS COMPANY (*Concluded*).

Lea Bridge (see L on Map, THE LANCET, May 8th, p. 1291, and Fig. 1).—The station at Lea Bridge is situated partly in the county of Middlesex and partly in Essex. It is bounded on the north by Lea Bridge-road, on the west by the Hackney Cut of the Lea Navigation, and on the south and east by the Hackney marshes. The station is divided into two parts by the River Lea, which is the county boundary. The Middlesex part of the station contains filter beds, a pumping engine, and turbines. The water which flows down the old course of the River Lea is regulated by sluices, one of which is situated at its juncture with the Hackney Navigation Cut, and the other at the point at which the river leaves the Company's property. The sluices are in charge of the Lee Conservancy Board. The part of the station which is situated in the county of Essex is divided into two by the aqueduct which brings the water from the Company's reservoirs at Walthamstow. The part of the station which is situated to the west of the aqueduct contains the offices of the Company, engine houses, and one set of filter beds. It is the custom of this Company to name their engines. Those which are situated here are the "Victoria," "Triples," "Prince," and "Princess." To the east of the aqueduct there are two sets of filter beds and an engine house for the "Duke" and "Duchess," the "Prince Consort" and horizontal engines. The well is also situated here. At the southern part of the station near the Lea a well is being sunk. The bulk of the water pumped from Lea Bridge comes from the Walthamstow reservoirs through the aqueduct (see Fig. 1), but a small quantity is

FIG. 1.

The Map shows the station at Lea Bridge. The letters C C C show the course of the culverts which pass from the aqueduct to the filter beds.

obtained from the deep well at this station. No water is taken from the River Lea at this point. The water from the aqueduct passes both to the Essex and Middlesex filter beds through culverts guarded by copper wire gratings of which the meshes are about $\frac{1}{10}$ in. in diameter. These gratings are

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., and XIII. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, 24th, May 1st, 8th, 15th, and 22nd, 1897, respectively.

Hosted by Google

cleansed twice every day and sometimes more frequently. The water to the Middlesex beds passes in an aqueduct under the Lea, and that for the Essex beds in the course marked in the map (see Fig. 1, C. C. C.).

Middlesex part of the station: Filter Beds.—There are six beds, which occupy six acres. The sides of the filter beds are built of brick at a slope of 1½ to 1. Each has a central and two lateral culverts to receive the filtered water. Water passes into these channels through perforated bricks. The filtered water well is 100 ft. in diameter, and is situated at the point marked by a circle in the centre of the nest of beds. The composition of the beds is the same as that of those at the Essex part of the station, and will be given with the description of them.

Pumping arrangements: "Victoria."—This is a Cornish pumping engine having a cylinder 100 in. in diameter and stroke of 11 ft. which works a pump of which the diameter is 50 in. This engine is used for pumping water through a stand pipe 48 in. in diameter and 120 ft. in height for the supply of the middle level district which embraces Mile End, Stratford, West Ham, Hackney and Bethnal Green. The head of water worked against is about 100 ft. The pump raises 150 cubic feet per stroke and works at a rate of 10 strokes per minute. The engine is therefore capable of pumping over 13,000,000 gallons daily. The steam is generated by eight Cornish boilers worked at the pressure of 35-40 lb. Some of the water used by the boiler is softened by the Porter-Clarke process.

Turbine house.—Near the "Victoria" engine house there is a house which contains two turbines which make use of the water power of the River Lea in flood time. The turbines are of the Girard type and work three plunger pumps 10 in. in diameter, which have a stroke of 2 ft. The pumping capacity is 20·4 gallons per revolution. In the same house a small turbine is worked by pressure from the water mains for the generation of electricity for lighting the station; the water thus used is returned again to the filter bed.

Water which was filtered at this station was formerly conducted by a culvert to the Company's station at Old Ford which has since been given up. The part of the aqueduct which is situated at the Lea Bridge station still remains and is used for another purpose. Into it the water from some of the filter beds is allowed to flow when they are emptied for cleansing purposes. In time of drought, when all the available water is required, this is pumped back on to the filter beds. The machinery used for this purpose is a portable steam-engine and two small hydraulic engines. There is an arrangement by which the hydraulic engines are set to work by means of a float; by this means the pressure of the water from the mains is used when necessary for pumping the water out of the old aqueduct back to the filter beds, and as the float arrangement works automatically no supervision is necessary.

The Essex part of the station.—There are three sets of filter beds on the Essex part of the station. Of these two sets are arranged round a central wall and, like the Middlesex beds are of somewhat peculiar form (see Fig. 1). The beds, forming the third set are more or less rectangular in form.

Old Essex Beds.—These six filter beds have a total area of six acres. The sides are built of brick with a slope of 2½ to 1. A channel for the filtered water runs in the centre of each and there are two lateral channels which conduct the water into the central one. The air ventilators in connexion with the filtered water channels pass through the side walls of the filter beds. There is no central ventilating shaft. The composition of the filter bed is as follows: Rough ballast, 9 in.; hoggin, 9 in.; sand 2 ft. When the sand is scraped off for cleansing purposes the total thickness is not denuded to a greater extent than six inches before the washed sand is replaced. The thickness of the sand used for filtration is not reduced to a depth of less than 1 ft. 6 in. The filter beds are during the summer cleansed about once a month, and once in six weeks during the winter months. The rate of filtration averages 1,000,000 gallons per acre in twenty-four hours. Another set of beds similar in all respects is situated to the east of the aqueduct.

New Essex Beds.—This series of filter beds consists of six, which occupy an area of about six acres. All these beds are oblong with rounded corners, excepting one which has an irregular form. The beds have concrete walls and are lined with Staffordshire bricks at the upper part. Each bed has one central air shaft as well as shafts in the side walls.

Cleansing sand.—At this station three methods are adopted: (1) sometimes the sand is washed by the water at a pressure of 100 ft.; (2) sometimes it is washed by water at low pressure "hand washing"; and (3) sometimes a special apparatus is used.

The pumping engines on the Essex side, to the west of the aqueduct, are the "Triples," the "Prince" and "Princess," and a set of turbines.

The "Triples."—The engine house is a light structure lined with white tiles. It contains three vertical triple expansion engines of which two are generally kept working, the engines are fitted with Corliss valve gear. The diameter of the cylinders is as follows:—high pressure 20 in., intermediate 34 in., low 57 in.; the stroke is 4 ft., and the diameter of the pump is 30 in. Each engine is capable of pumping 357 gallons per stroke and the rate at which the engines work is from sixteen to twenty-four revolutions per minute. The head of water worked against is about 100 ft., and the engines are used for pumping to the district. The amount which can be pumped daily by each of these engines is 12,000,000 gallons. Steam is generated by six Lancashire boilers which work at a pressure of about 120 lb.

"Prince" and "Princess."—The house containing these engines is situated just at the east of the offices. The engines are of the Cornish type; the diameter of the cylinders is 84 in., and the stroke 11 ft. They pump water into a stand-pipe 140 ft. high, which is situated in the chimney. The head of water worked against is generally about 140 ft. The steam is generated by ten Cornish boilers, which work at a pressure of from 38 to 40 lb. These engines work two pumps, of which the plungers are 45 in. in diameter and the stroke 9 ft., the rate being generally nine or ten strokes per minute. The amount of water pumped is 623 gallons a stroke. The engine house contains an electric indicator for recording the height of water in the reservoir at Finsbury Park.

Turbines.—Two Hercules turbines actuate two sets of double-acting pumps, which deliver 26 gallons of water per revolution into the mains supplying the Essex district. The head of water worked against is generally about 180 ft.

At the part of the station to the east of the aqueduct are situated the well, the "Duke" and "Duchess" (horizontal) and "Prince Consort" engines. There is also a residence for the foreman of the Lea works.

"Duke" and "Duchess."—These are two compound engines of which the diameters of the cylinders are 23 in. and 39 in., the length of the stroke being 4 ft. 6 in. and 6 ft. 6 in. These engines work bucket and plunger pumps. The diameter of the buckets is 2 ft. 3 in. and of the plunger 1 ft. 7 in.; the stroke is 5 ft. 7 in. Each delivery therefore amounts to about 139 gallons. The head of water worked against is 174 ft., and the water is pumped to Haggar-lane, Woodford, and Forest Gate. In an adjoining house there is a compound horizontal tandem engine having cylinders with the respective diameters of 23 in. and 40 in. and a stroke of 3 ft. This engine works pumps of which the diameters are 22 in. and the stroke 3 ft. The amount pumped per revolution is 99 gallons. The engine is used as an auxiliary for pumping to Haggar-lane.

Well.—The well is 200 ft. in depth. It has two series of headings—one series at a depth of 200 ft. from the surface and the other at a depth of 140 ft. Altogether there are 7000 ft. of headings. One canal goes in the direction of Walthamstow, the second in an easterly direction, and the third towards the south-west. This well is only used when there is a scarcity of river water. The amount of water pumped from it has been as great as 3,000,000 gallons per day. The engine used for raising the water is a compound tandem well engine, which has cylinders of 24 in. and 44 in. in diameter respectively and a stroke of 6 ft. The pump is worked through bell cranks. The diameter of the bucket is 22½ in. and the length of the stroke 6 ft. The capacity per stroke for the pumps is 206·6 gallons. This engine, the "Duke" and "Duchess," and the tandem engine are worked by steam generated by two Lancashire and three Cornish boilers worked at a pressure of 70 lb.

"Prince Consort."—This engine received its name from the fact that it assists the "Victoria." It is of marine type, with cylinders of 21 in., 33 in., and 56 in. respectively in diameter, it has a stroke of 3 ft. 3 in., and works three plunger pumps which have strokes of 3 ft. 3 in. and a capacity of 361 gallons per revolution. The steam for working the engine is generated by three Lancashire boilers, one of which is fitted with an automatic stoker. The steam-pressure used for working the engine is 125 lb. The head of water worked against is 107 ft. and the water supplies the district

Hosted by Google

directly without the intervention of any reservoir or standpipe.

The works at Lea Bridge are fitted with an apparatus for carrying coal from the Lea Navigation Canal. The arrangement, which works well, is that a continuous chain provided with lateral arms runs in a cast-iron channel; in this way the coal is conveyed from the barges to elevators which are situated at the engine house. At the eastern extremity of the Company's premises there is a line of rail which joins the Great Eastern Railway; some coal comes in this way by trucks.

Meter house.—There is a house at this station fitted up for testing taps and meters. It was found by the engineer of the Company that a very large amount of water was wasted in the districts supplied because the taps which were fixed in the dwellings of the poor were of very inferior quality and soon got out of order. When this was the case there was, of course, a continual loss of water. The Company tests any taps which are sent for that purpose. They are re-leathered without expense to the customers.

Offices.—The office of the chief engineer and the draughtsman's room are situated at Lea Bridge, and the station is in electric communication with the City offices and the stations at Walthamstow, Chingford, and Haggar-lane.

Waltham Abbey (see D on Map, THE LANCET, May 8th, p. 1291).—The station at Waltham Abbey is situated just at the west of the Lea Navigation Canal and opposite the Government Cordite Factory and about half a mile to the south of the Abbey Church. Here there is a well 200 ft. in depth, with about 600 ft. of headings running in various directions under the property of the Company. There are ten bore holes which pass from 90 ft. to 150 ft. below the level of the heading. The upper part of the wall is lined with iron cylinders 10 ft. in diameter. Chalk occurs at 123 ft. below the surface of the ground which is here 65·5 ft. above ordnance datum. The upper 80 ft. of the well has outside the cylinders an external lining of brick and cast-iron cylinders, of which the diameter is 11 ft. Water is pumped by a triple expansion engine of marine type, which has cylinders with diameters of 18 in., 30½ in., and 51 in. respectively, and a stroke of 3 ft. The deep well pumps are worked off the main shaft by bell-cranks. There are two pairs of buckets of which the diameters are 18 in. It may be of interest to note that this is the first triple expansion engine which was ever erected for pumping water. The steam for working the engine is generated by four water-tube boilers. The amount of water raised daily is about 750,000 gallons, and it is pumped to the districts of Waltham Abbey, Loughton, Woodford, Buckhurst Hill, and Chigwell. The head of water worked against is about 330 ft. On May 12th the engine was being overhauled and was not at work. The engine house is very well lighted by large windows and is lined with white tiles. For artificial lighting electricity is generated by a small vertical high-speed engine. A cottage for the foreman is situated here.

High Beech (see H on Map, THE LANCET, May 8th, p. 1291).—Here is a reservoir capable of holding 2,500,000 gallons of water. It is covered with brick arches and turfed over. The top water line is 371 ft. above ordnance datum. Water is pumped here from Waltham Abbey and from Haggar-lane, and it goes to supply the Essex high-level district.

Buckhurst Hill (see I on Map, THE LANCET, May 8th, p. 1291).—There is a reservoir at Buckhurst Hill capable of holding 800,000 gallons of water. It is covered with brick arches and turfed over. The top water level is 271 ft. above ordnance datum.

Hornsey Wood (see C on Map, THE LANCET, May 8th, p. 1291).—This station consists of a covered reservoir situated in the south-east part of Finsbury-park, near the Seven Sisters-road. It is of oblong form and covered by brick arches. It is capable of holding 5,000,000 gallons. The top water-level is 141 ft. above ordnance datum. The Thames water is pumped here from the Hanworth station through a 36-in. main, and the Lea water from Lea Bridge through a 30-in. main. It serves for the supply of the western part of the Company's district. There is an electric indicator which shows the height of the water in the reservoir, the index is at the station at Lea Bridge. The communicating wire passes underground to Harringay Station, then along the Midland Railway to the Lea Navigation Canal and down the towing path. The reservoir is turfed over, and there are tennis courts over it. The surface of the ground is in the possession of the London County Council.

Haggar-lane (see J on Map, THE LANCET, May 8th, p. 1291).—At this station there are two reservoirs, and machinery for pumping to High Beech. The older of the reservoirs is capable of holding 3,000,000 gallons the top water-level is 171 ft. above ordnance datum. It is covered with brick arches which have a layer of earth, with a little grass growing on it. The newer reservoir has a capacity of 7,000,000 gallons and the top water-level is 181 ft. above ordnance datum. It is covered with arches built of concrete and supported by steel girders. A layer of burnt clay has been placed on the top. The reservoirs are supplied with water from Lea Bridge, and from Walthamstow.

Pumping arrangements.—There are two horizontal condensing engines with 24-in. cylinders which work plunger pumps. The steam is generated by five Cornish boilers working at a pressure of 50 lb. The water is pumped for the supply of the High Beech reservoir and district, and occasionally to Buckhurst Hill reservoir. The head of water worked against in pumping to High Beech is 205 ft. As a rule one engine only is used. It is worked night and day and pumps about 500,000 gallons of water. The grounds of this station are about five acres in extent; they are fenced in and planted with trees. There are two cottages for employés of the Company, and a small workshop.

Communications with other companies' mains.—There are two communications with the mains of the Grand Junction Water Company: (1) at Kew; (2) at Campden Hill. The company can also, if necessary, supply the New River Company with water at Stoke Newington. If this were done the filtered water used by the East London Waterworks Company would pass into the New River and would be filtered again in the ordinary course by that company. This communication has, however, never been used. The New River Company have indirectly supplied the East London Company with unfiltered water when there has been a lack of it. The arrangement made simply was that the New River Company did not take the whole of the amount of water they were authorised to take at Ware, and so the water was allowed to flow down the Lea and was received at the ordinary intake of the East London Waterworks Company at Chingford. Last year during the drought the New River Company supplied water to a considerable amount in this way.

Length of new pipes.—The length of new pipes ranging from 3 in. to 24 in. laid in 1895 was 24¼ miles and during the year 1896 was 21¼ miles.

Hydrants.—The number of hydrants erected during the year 1895 was 15 and during the year 1896 it was 1406.

Houses under constant supply.—The number of houses under constant supply on Dec. 31st, 1894, was 179,167; on Dec. 31st, 1895, 180,500; and on Dec. 31st, 1896, 186,364.

Percentage of houses under constant supply.—On Dec. 31st, 1896, the percentage of houses under constant supply was 99.

Highest supply given.—The highest supply given is at High Beach, 370 ft. above ordnance datum.

Average daily supply per head.—The average daily supply per head for the year 1896 was 33 gallons. These figures are arrived at by the engineer of the Company, as follows. The amount of water supplied is estimated from the known volume delivered by the pumps. The population is estimated from the figures given at the last census, with an addition for the new houses supplied. It is generally known that in different districts the average number of people per house differs very widely. As a rule, however, this fact is not allowed for by water companies in estimating the amount of their water-supply—that is to say, a general average figure is taken to represent the whole district under supply. In the case of the East London Company an attempt is made to find the average of the population per house in each district which is supplied by the Company. In this way a factor is found which is used in the calculation of the increase in each separate district. The population is worked out for each month in the case of each district supplied by the Company and the mean population is obtained by adding together the numbers arrived at for each month and dividing the whole sum by twelve.[2] This method of calculation of course involves a very large amount of clerical work.

Dates of the maximum and minimum supply.—The following

[2] The average population per house in different districts supplied by the Company is found to be: Shoreditch 8·90, West Ham 6·39, East Ham 5·95, Wanstead 5·68, and Leyton 5·83.

Hosted by Google

table give the date of the maximum and minimum supplies and the average daily quantities supplied.

—	Year 1895. Month.	Year 1895. Quantity in gallons.	Year 1896. Month.	Year 1896. Quantity in gallons.
Maximum ...	February	59,160,000	June	46,870,000
Minimum ...	August	40,750,000*	August	32,760,000*

*Intermittent supply during drought. *Intermittent supply during drought.

Table of Statistical Details given by the East London Waterworks Company for the Year 1896.

SUPPLY.	Average daily supply in gallons...	40,000,000 gallons*
	Percentage delivered for other than domestic purposes, exclusive of waste	About 23 gallons
	Number of houses supplied	138,435
	Number of houses on constant supply	186,798
	Estimated population supplied	1,251,000
RESERVOIRS. Subsiding and storage unfiltered water	Number	9
	Area in acres...	238
	Available capacity in gallons	815,000,000
Storage filtered water reservoirs	Number	7
	Capacity in gallons	13,800,000
ENGINES.	Number	31
	Horsepower	5590
	Greatest lift	500
	Head of pressure in the district supplied	40 ft. to 350 ft.
WATER-PIPES.	Total number of miles of water-pipes	897
	Number of miles of water-pipes in the metropolis...	456
	Number of miles of streets with water-pipes constantly charged in the metropolis	185
	Number of hydrants erected within the metropolis...	3628 public; 2761 private; and 7076 fire plugs
FILTERS.	Number of beds	34
	Area in acres...	31
	Depth of sand and other materials	2·0 ft. sand, 0·6 in. hoggin, and 1·0 foot coarse gravel

* This figure is lessened by reason of the drought causing the interruption to the constant supply in July, August, and the beginning of September.

East London Company.—The Act of 1853 authorises the East London Company to supply the following places:—

Supplied.—Artillery Ground, Bethnal Green, Bow, Bromley, Chigwell, Chingford, Clapton, West Ham, East Ham, Homerton, Leyton, Leyton (Low), Leytonstone, Limehouse, Loughton, Mile End (Old Town), Mile End (New Town), Old Ford, Poplar, Ratcliff, St. George-in-the-East, Shadwell, Spitalfields, Stamford Hill, Stepney, Stratford-le-Bow, Walthamstow, Waltham Abbey, Waltham Holy Cross, Wanstead, Wapping, and Woodford.

Partly supplied.—Hackney, Whitechapel, Bishopsgate, Ilford, St. Botolph Aldgate, Shoreditch, Tottenham, and Woolwich (north of the Thames).

Not supplied.—Islington, Newington, St. Luke Old-street, Barking, Dagenham, Dalston, Holloway, Kingsland, Romford, Shacklewell.

The Company occasionally supplies a small amount of water in bulk to the Cheshunt Urban District Council, Hertfordshire.

NEW WORKS IN PROGRESS.

Walthamstow (see K on Map, THE LANCET, May 8th, p. 1291).—A reservoir which will be called Warwick West is approaching completion at Walthamstow. It will have an area of thirty-seven acres and be capable of holding about 200,000,000 gallons. It will be supplied with water from No. 5, the Racecourse, and the East Warwick.

Lea Bridge.—Near the "Prince Consort" engine house a well is in course of construction. The depth at present is about 145 ft., and the chalk was reached at 85 ft. The diameter of the well is 12 ft., and iron cylinders have been sunk to the level of the chalk.

Rammey Marsh (see E on Map, THE LANCET, May 8th, p. 1291).—A well is being sunk at Rammey Marsh. The ground level here is 53 ft. above ordnance datum. The well has reached a depth of 66 ft. from the surface, and at this depth the work is still being carried on in the London clay. There was about a foot of surface soil, and 18 ft. of ballast above the London clay. The upper 25 ft. of the well is surrounded by iron cylinders, of which the diameters are 15 ft., and brickwork, of which the internal diameter is 14 ft.; the lower part is lined with iron cylinders, of which the outside diameters are 12 ft.

Ponder's End (see F on map, THE LANCET, May 8th, p. 1291).—The new station here is situated at a level of 40 ft. above ordnance datum. A new well is being sunk here; the depth reached is 109 ft., at which level chalk has been reached.

Barking (see M on map, THE LANCET, May 8th, p. 1291).—This place is situated at 10 ft. above ordnance datum. A new well is being sunk here. The depth reached is 200 ft. Some headings have been driven at the bottom of the shaft. Chalk was reached at a level of 145 ft.

Ferry-lane.—At this station a new well is being sunk; the depth now reached is about 140 ft., and at this depth the upper level of the chalk is situated.

THE LANCET SPECIAL COMMISSION ON SICILY AS A HEALTH RESORT.

IN the year 1895 a number of Sicilian gentlemen of high rank and social position formed themselves into an association with the object of promoting the progress of their country, and more especially with the view of developing it as a health resort. This body entitled itself the "Associazione pel Bene Economico," and its members were as follows: Count Mazzarino (President), Mr. Joshua Whitaker, Commendatore Ignazio Florio, Signor Giovanni Guccia, Prince Scalea, Count Caltanissetta, Commendatore Ignazoi Greco, Cavaliere Alberto Ahrens, Prince St. Elia, Count Ferdinand Monroy, Signor Guglielmo Helg, Commendatore Eugenio Oliveri, Cavaliere Michelangelo Siciliano, Cavaliere Napoleone La Farina, Cavaliere Carlo Albanese (secretary), and Signor Lo Presti (vice-secretary).

It seemed to the members of this influential association that one of the most effective means of accomplishing the ends which they had in view would be to have a thorough inquiry instituted by some independent and competent authority into the climatic, hygienic, sanitary, and other conditions prevailing in the Island of Sicily, and that the results of this inquiry should be made public through some authoritative channel. With this purpose the association approached the Editors of THE LANCET and invited them to send a Special Commissioner to Sicily for the above object. Believing that such a Commission would not only be likely to benefit the Island of Sicily, but also to advance the interests of medical science, we willingly acceded to this request of the "Associazione pel Bene Economico." Our Special Commissioner in due course arrived in Palermo, where he was most kindly received by the representatives of the Association, who took instructions from him regarding the objects and methods of his Commission and who facilitated his investigations and inquiries by every means in their power. We feel specially indebted to Mr. Joshua Whitaker and Cavaliere Carlo Albanese for the great amount of time and labour which they devoted to forwarding the work of this Commission. The method pursued by our Special Commissioner was as follows:—

1. The collection of all the available data bearing upon the meteorology and climatology of Sicily. For this purpose the admirable records of the various

Hosted by Google

meteorological observatories in the country were found to be of great value. Several of these observatories were visited personally by our Special Commissioner and all records were freely put at his disposal. To Professor De Lisa of Palermo he is specially indebted. Full particulars will hereafter be given regarding meteorological observations at the following places: Palermo, Catania, Syracuse, Girgenti, Termini, and Taormina.

2. The collection of information relating to the flora and geology of Sicily, in so far as such information would be likely to throw light upon the climatic and hygienic condition of the island. The various botanical collections were inspected, and our Special Commissioner feels particularly indebted to Professor Borzì, Director of the Orto Botanico of Palermo, both for his personal courtesy, and for the valuable memorandum which he has furnished regarding the special features of the Sicilian flora and the remarkable results of experiments in acclimatisation made at Palermo.
3. The collection of statistics relating to the state of public health in the various localities, drainage, sanitation, prevalent diseases, and the results of treatment in the case of invalids wintering in Sicily.

The medical profession in Sicily responded most kindly to the inquiries of our Special Commissioner, who owes valuable information especially to the following gentlemen: Professor Giuffrè (Palermo), Professor Cervello (Palermo), Professor Ughetti (Catania), Professor Lancetta (Girgenti), Professor Perez (Palermo), Dr. Migneca (Catania), Dr. Menzalora (Termini), Dr. Formica (Girgenti), Dr. Palumbo (Castelbuono), Dr. Marchesano (Palermo), Dr. Berlin (Palermo), Professor Mattei (Catania), Professor Manfredi (Palermo), Dr. Martinez (Girgenti), Dr. Cacciola (Taormina), Professor Ciofalo (Termini), Dr. Corselli (Palermo), and others.

4. Inquiries into the mineral springs of Sicily, the various sources of water-supply, methods of distribution, &c. The results of the examination in THE LANCET laboratory of the chief potable and mineral waters of Sicily, specially forwarded for the purpose, will form portion of the reports of our Special Commissioner.
5. An inquiry into the nature of the accommodation available for invalids and other travellers.

Our Special Commissioner personally visited the principal localities in Sicily in addition to Palermo—viz., Catania, Girgenti, Syracuse, Messina, Taormina, Castelvetrano, and many others.

His reports are in a forward state of preparation, and we hope to commence their publication in an early issue. We believe they will be found to comprise the most complete account of Sicily—from the climatic and hygienic point of view—which has hitherto been published.

In addition to the gentlemen already mentioned we desire on behalf of our representative to acknowledge his indebtedness for information and assistance of various kinds to the following:—Count Mazzarino, Dr. W. W. Baldwin (Florence), Professor Zona (Palermo), Professor Gemmellaro (Palermo), the Marchese di Gallidoro, the Marchese Antonio di Gregorio, Signor Emmanuele Calcagno (Palermo), Ingeniere Ignazio Greco, Ingeniere Enrico Bottone D'Anna (Palermo), Mr. Sammuele Hamnett (Palermo), and Signor Cipollina (Girgenti).

THE SANITARY CONVENTION OF VENICE, 1897.

No. III.[1]

BESIDES the general maritime regulations which are framed with the view of preventing the importation of plague into Europe and of controlling that disease, should it unhappily make its way into the basin of the Mediterranean, the Venice Conference arrived at a large number of conclusions which aim at preventing any spread of the disease through the agency of the pilgrimage to Mecca. In view of the immense Mussulman population under British rule, and of the fact that ports on the west coast of India are largely resorted to as starting-points by pilgrims from countries north and north-west of British India, these conclusions have an important concern for this country. They are, in the main, based upon the conclusions of the Paris Convention of 1894, which aimed at controlling the spread of cholera by the pilgrimage, but they are to some extent modified by reason of the fact that the period of incubation for plague is deemed to be twice as long as that for cholera.

Roughly speaking, the measures embodied in the Convention may be divided into action taken at ports of departure, during the voyage, and on the return journey. In the first place, pilgrim vessels are defined, their construction and sanitary arrangements are strictly controlled; the upper deck must be kept clear for pilgrims, and on the main covered deck every pilgrim is to have at least sixteen square feet of surface. Every one going on board has to pass a medical examination; female medical practitioners are to be employed in the case of women pilgrims; no sick person, or person suspected of infectious sickness, may go on board; the number for which the vessel is licensed is set out, and the names of all passengers are inscribed on board. Provision is made as to the quality and cost of food supplies and also as to the wholesomeness of water, of which a proper quantity must be gratuitously provided. A portion of the vessel has also to be set apart for cases of sickness needing isolation. Every pilgrim vessel must carry one medical man or more and a disinfecting stove on board. Many details are set out as to the medical inspection, disinfection, and measures of cleanliness to be maintained during the voyage; and then come the regulations as to landing of all the pilgrims at the island of Camaran in the Red Sea before proceeding on the last stage of the voyage to Jeddah. Much discussion has taken place during recent years as to Camaran, many holding that this so-called sanitary station has been little better than a hotbed of disease and a source of danger to pilgrims, who are besides subjected to many extortions there by Turkish officials. Hitherto all pilgrims have had to stay there ten days under supervision, but that is now reduced under the Venice Convention to three days; and the detention of pilgrims from healthy vessels is only intended to cover sufficient time for cleansing the persons and linen of the pilgrims once more by baths and otherwise before they continue their voyage. But nearly everything at Camaran depends on the action to be taken by Turkey, the Government of which has, subject to certain reservations, now intimated its acceptance both of the Paris and the Venice Conventions. It must be admitted that the Turkish administration is at last making a move at Camaran, but much pressure will probably have to be exercised before all is done that will make the stay of large bodies of pilgrims at that station even safe.

But assuming that no disease appears during the three days' stay there, then the pilgrims embark again and go straight to Jeddah. If disease has appeared either before or after landing at Camaran, the pilgrims are detained for at least ten days from the date of the last case. At Jeddah matters pass beyond the influence of international conventions, for from that point forward the pilgrims are on Turkish territory and must submit to Turkish rules and demands. But having regard to the notorious sanitary defects at Jeddah, Mecca, and elsewhere, and to the cruel loss of life which is a necessary result of the land stages of the pilgrimage, urgent recommendations have been made to the Sultan to use some at least of the large sums taken from the pilgrims as sanitary dues and in other ways in providing somewhat better for their obvious needs.

The convention deals with a large number of other sanitary stations in the Red Sea. But since these have to do either with the Mussulman pilgrims from the Dutch Indies, or with those coming from countries bordering on the Mediterranean, they have only a very indirect interest for this country. As regards the return journey of our Indian pilgrims no restrictions are necessary, for the Indian Government desire, in the pilgrims own interests, to let them go on board again as soon as practicable. But the restrictions on pilgrims returning north, or into Egypt, are numerous and severe.

Whether plague or cholera is in question one of the greatest dangers that has to be faced lies in the land routes across Mesopotamia and the Arabian Desert, and in the resulting caravans. Rules are laid down as to the control of

[1] Nos. I. and II. were published in THE LANCET of May 1st and 15th, 1897.

Hosted by Google

these at frontiers and other places; but having regard to the uncivilised nature of the countries and peoples in question it is hardly likely that anything material will be done along many of these routes for the prevention of disease and for the maintenance of proper sanitary conditions amongst the pilgrims. The conclusions relating to land traffic and land frontiers and to the practices of disinfection which are advocated in the Convention have a somewhat closer concern and interest for us. The frontier between European and Asiatic Russia has always been a source of anxiety when cholera has travelled northward and westward from British India, and it has become still more so since the railway was laid down from Turkestan to the shores of the Caspian. Should plague move in that direction, the danger will be much the same, and though we may think some of the regulations as to land frontiers excessive in their requirements, we must remember that there are none that we are obliged to impose ourselves, and that as regards some land frontiers great public health interests are involved. But it has fortunately been decided that there are to be no more land quarantines. When exotic disease is prevailing, the worst thing that can be done is to aggregate people together under conditions which alone are available on most land frontiers. Hence it is laid down by the Convention that whilst land quarantines are abolished, their place should be taken by modern methods, such as medical inspection, disinfection of infected and suspected articles, &c. Where railways run across frontiers this will be practicable, but there are other frontiers where it would be impossible to establish the necessary organisation at the several points where land traffic and movements of people take place. Hence the Convention meets such a case by permitting any country to close its land frontier either at specified points, or altogether, when plague is prevalent in an adjoining state. This, in our opinion, is preferable to resorting to the antiquated and often cruel system of land quarantine.

The principles of disinfection laid down by the Convention are fairly modern ones. But in their application they are largely permissive, and it is quite possible that action that *may* be taken by one or another country goes beyond anything that we deem necessary or shall ever take in this country. The fear of infected linen as a vehicle of disease is great on the continent, and since every article that has been worn is looked upon as soiled and hence possibly infective, very harassing restrictions may come to be imposed on travellers. But whilst this country cannot impose its views on other ones in this matter, we have at least the satisfaction of knowing that, with very few exceptions, disinfection is purely permissive and not obligatory, and that we, though adhering to the Convention, can have none of these excessive measures forced on us to be adopted in our own country. Indeed, almost the only articles the disinfection of which on admission to a country is compulsory on the contracting Governments are articles of clothing travelling by parcel post. With us these are often the clothes of English soldiers and sailors who have died in India, and they are admittedly so dangerous when plague is about that our Post-office regulations for the moment altogether prohibit their dispatch from India. The question of merchandise may also be regarded as satisfactory. Contracting Governments are not obliged to prohibit the importation of any single article; but there are certain things that any country may prohibit if it chooses, such as rags, sacks, carpets, &c. that have been in actual use, fresh and untanned leather, and the débris of animals, such as hair, hoofs, &c. In this country we have very little belief in danger even from these articles, and we have as yet placed no prohibition upon their importation. But we cannot force this view on others, although we may deplore that Indian merchandise of the sort referred to should be refused entry into other countries, even though plague may prevail in the port of shipment or in the country whence the articles are derived. Happily it is laid down that all letters and postal correspondence are to be altogether unhindered, and thus we avoid the silly practice of fumigating sacks which hold letters and which have in advance been made impenetrable to any fumigating material by reason of their having been coated with tar. Many similar trivial practices are condemned by the Convention which exhibits a very distinct stage of advance in the direction of modern opinion based on increasing scientific knowledge.

With the results of the Convention, in brief, the British public health administration has distinct reason to be satisfied. It, of course, contains provisions, the application of which is permissible, which we in this country have long since discarded; but it imposes on us nothing that we hold to be undesirable or unnecessary. Some countries can, under the Convention, take action which we shall regret, and which, whilst affording them no real protection, will tend to hinder new commerce; but it is clear that previous Conferences have done much to educate retrograde advisers of other States up to a standard which approaches much nearer to our own than we could have anticipated; and we may reasonably look forward to a time when the repeal or further ratification of existing Conventions comes round, at which even further advance will be made in the only direction that has an intelligibly scientific and practical basis on which to rest.

THE USE OF INCUBATORS FOR INFANTS.

THE employment of incubators as a means of saving the lives of prematurely born or of very weakly infants has not yet become general in England. Yet it is notorious and obvious that the best, almost the only, means of saving such infants is to protect them absolutely from change of temperature and from cold. For such purposes children used to be wrapped up in wadding or in a sheep skin with the wool adhering. The peasants of Silesia and Westphalia sometimes placed infants in a jar full of feathers. In England the cot or cradle was put close to the hearth, and it was necessary to watch the fire day and night so that the temperature might not vary. The use of hardware hot-water bottles inserted in the bedding of the cot is also a very general practice, and this method is adopted in many maternity and other hospitals. But such devices are not uniformly reliable; their success depends upon the intelligence and assiduous care of the attendant, and the accidental opening of doors or windows, an unexpected and sudden gale, or a fall of temperature may defeat the effect even of the most elaborate precautions. Some sixty years ago, however, Dr. Crédé, of the University of Leipzig, sought to effect an improvement on these primitive and unreliable methods. He constructed a sort of box with double metallic sides; the space between these walls could be filled with hot water so as to maintain the desired temperature within the box. The infant, covered with blankets and resting in a basket or cradle, was placed inside. Incubators of this description are still employed at the Charity Hospital, Berlin. In 1878 Dr. Tarnier, when visiting the artificial couveuses installed by M. Odile Martin at the Jardin d'Acclimatation for the rearing of poultry, thought that he might utilise a similar apparatus in the case of prematurely born children. M. Odile Martin was therefore requested to construct a couveuse sufficiently ventilated and large enough to hold one or two infants. This was done, and the first couveuses were introduced at the Paris Maternity Hospital in 1880. They constituted a noteworthy step forward in the right direction, but the apparatus had to be warmed anew three or four times a day, and its successful employment depended on the care and watchfulness of the attendant. Good results nevertheless ensued and many lives were saved. Dr. Vallin, in a report presented to the Academy of Medicine of France (Nov. 12th, 1895), said: "We are obliged to regard as prematurely born all infants who do not weigh at birth 2 kilogrammes 500 grammes (5 lb. 9 oz.), and they are numerous, for the proportion is set down at from 15 to 30 per cent. of the births. The minute and delicate care which these weakly infants require, especially in winter, to protect them from cold is so great that till now most of them have died"; but Dr. Vallin added that "since Dr. Tarnier introduced at the Paris Maternity Hospital the ingenious contrivance called a 'couveuse,' a large number of these infants have been saved. This apparatus, however, cannot be readily employed. It is necessary that a number of experienced persons shall be always in attendance, for a delay of twenty-four to forty-eight hours might result in the death of the new-born infant." Dr. Jules Rouvier, of Beyrouth, in his interesting paper on Infant Mortality, read at the International Congress of Hygiene held at Budapest in 1894, estimates that among the newly born debilitated infants are in the proportion of 5 per cent. Of these infants born in a state of enfeeblement

Hosted by Google

only 20 per cent., according to Uffelmann, live twelve months, and 11 per cent. two years. The greater number die during the first day or the first week of their existence. Of 1961 children born at the Paris Maternity Hospital, in 1881—that is, before the introduction of the couveuse—641 were premature births. The mortality during the first two weeks of the prematurely born amounted to 32 per cent.; that of the other infants was equal to 8·62 per cent.

In England the question of incubators is of particular interest, for though the general death-rate of infants has decreased considerably of late years, the death-rate due to premature births has, on the contrary, greatly increased. This increase has been set down by some authorities as equal to 40 per cent. The London tables of mortality show that whereas the deaths registered as due to premature birth amounted to 1930 in 1886, this figure rose to 2534 in 1896. To this we should also add that a large though unknown number of deaths attributed to various diseases are indirectly caused by premature birth. Under these circumstances any successful attempt to improve the construction of incubators and to render this life-saving apparatus available to the general public must be welcome. That this has been achieved will, we are informed, shortly be rendered evident by a remarkable exhibit at Earl's Court. A structure is now in the course of erection just opposite the Welcome Club, where infants prematurely born will be nursed and kept in new and model couveuses. The main feature of this new incubator is the fact that it requires no constant and skilled care. It works automatically; both ventilation and heat are maintained without any fluctuations whatsoever, not only for hours, but even for days. The incubator need not be touched for these purposes, and the only attendance necessary is that needed for feeding and washing the infant. The heating is produced by hot water, which circulates in copper piping placed at the bottom of the incubator under the cradle or hammock. This pipe is fed by a water boiler, which stands outside the incubator, and may be heated by an oil lamp, by gas, or by electricity. The temperature is automatically maintained at the required heat by a specially constructed thermostat. This is made in the shape of a W composed of two metals, the one being quick to expand and the other to contract. One side of the W is fastened to the wall of the incubator. The W, thus standing out from the wall, widens with heat and contracts with cold. The loose end of the metallic W is connected with a system of levers. On the outside a very light chain hangs to the lever that comes through the wall of the incubator. When the temperature inside the incubator is beginning to exceed the limit for which the apparatus has been set—and this limit can be varied according to circumstances—the W thermostat expands and so works on the levers that the chain is drawn upwards, and by this action the gas or the lamp is turned down and the supply of heat to the boiler is decreased. The temperature within the incubator consequently begins to go down. The thermostat then contracts, the chain falls, and the gas or lamp is turned on again to the full. Thus whatever changes may occur outside the incubator the temperature within regulates itself. So delicate is the construction of this thermostat and the levers attached that the slightest variation of temperature suffices to set it in motion. Thus the heat within the incubator never varies more than two degrees Fahrenheit. Another system consists in having a hollow centre passing through the boiler, and the burner is placed in this aperture. The opening is closed at the top by a cone-shaped lid attached to the chain. When the thermostat expands it lifts this lid, so that the heat passes through and the water begins to cool.

To ventilate the incubator there is a pipe, which is conducted through the wall or window of the house or hospital. Only air taken outside the building is supplied to the infant within the incubator. When we consider how often private houses, and even hospital wards, are inefficiently ventilated, it is not necessary to insist on the advantage of deriving the air-supply direct from the street or garden. This pipe, about four inches in diameter, delivers the outside air into a box fastened to the side of the incubator. The air is first moistened and washed by being passed through a layer of absorbent wool suspended over a saucer containing water or an antiseptic solution. A little further on there is another sheet of wool, which, however, is dry and serves to retain the soot and other particles floating in the air. From this filtering box a second pipe delivers the air into the bottom and centre of the incubator. Just above this inlet a disc is suspended, which breaks up the current of air and diffuses it in all directions and over the surface of the hot-water coils. Thus, the air is washed, filtered, and warmed before it reaches the infant lying above in the upper part of the incubator, and is uniformly distributed so that there is no sudden current in any one direction. On the top of the incubator a chimney about three feet long forms the outlet, and so that this should not accidentally become an ilnet, admitting a downward draught, a revolving screw-fan is placed within this flue, which only turns to allow the outward passage of an upward current. Thus it will be seen that, so long as the lamp or the gas burns, the temperature and the ventilation within the incubator will be automatically maintained. The incubator is made of glass and metal, and, therefore, it can be washed and disinfected with the greatest promptitude and facility. It is so portable that it can be readily carried from room to room, or placed in a cab, and taken to any house wherever required. As no skilled attendance is needed it can be used in private families as well as in hospitals. So far incubators have been available only for the rich or the poor. For the great middle class, persons who are not rich, but who are not poor enough to go to the hospital, there are as yet no incubators available. It is proposed, however, to meet this difficulty. In London and in other large centres incubator stations will be established. In response to a message or a telegram incubators will be despatched immediately wherever they are required. This will not occasion any great expense, for the incubators need not be bought nor will it be necessary to pay for skilled attendants. The incubators will be let out on hire for the number of days they may be required, and thus it may be possible to save the lives of many prematurely born or particularly delicate infants.

HISTORICAL NOTES ON MEDICINE, SURGERY, AND QUACKERY.

IV.[1]

AT the commencement of the present century St. Anne-street was the most distinguished thoroughfare in Liverpool, and was looked upon as a rival to Rodney-street. It so continued until 1835, when the tide of fashion began to sweep southward and afterwards extend towards Aigburth. In St. Anne-street resided Thomas Stewart Traill, M.D., an eminent physician and a ripe scholar, as did his brother-in-law, Mr. Sandbach, the merchant prince, who was mayor in 1831, and whose house was the first erected in the street. Dr. Traill was professor of chemistry in the Liverpool Royal Institution and lecturer in different branches of natural philosophy. He was physician to the Liverpool Ophthalmic Infirmary. Several valuable papers by him appeared in the memoirs of the Wernerian Society, in the *Edinburgh Philosophical Journal* and in other works. On leaving Liverpool he went to Edinburgh, where he became professor of medical jurisprudence and edited an edition of the "Encyclopædia Britannica." There is a fine portrait of this gentleman in the Royal Institution, Liverpool. There is also a bust of him extant. At a public meeting, convened with the concurrence of the leading men of all parties, held in the music hall, Bold-street, on June 8th, 1825, the subject of establishing a Mechanics' Institute in Liverpool was introduced by Dr. Traill in a clear and lucid speech. Other speakers addressed the crowded and enthusiastic assembly. An influential committee was formed, Messrs. John Gladstone, M.P., and John Moss, with Dr. Traill, being appointed vice-presidents. The institution was immediately organised, and flourishes to-day as the Liverpool Institute in Mount-street. The name of Dr. Traill appears among those of the gentlemen who cordially supported Mr. Sandars, when he projected the Liverpool and Manchester Railway.

At a public meeting, held in Liverpool on Dec. 14th, 1830, for promoting the cause of Reform in Parliament, Mr. Thomas Blackburn, surgeon, opposed the ballot, observing that a "man ought to vote openly and boldly, and if the right of voting were given to the wealthy and intelligent members of

[1] Nos. I., II., and III., were published in THE LANCET of March 6th, March 27th, and April 10th, 1897, respectively.

Hosted by Google

the community the vote by ballot would be quite unnecessary. No reform of the House of Commons would have any good effect which did not render the vote by ballot absolutely unnecessary." The last election in Liverpool had cost the two candidates about £115,000.

Rodney-street has always been a favourite locality of the medical profession. Towards the close of the last century the district of Rodney-street, Upper Duke-street, and Hope-street was all unbuilt upon, being in some parts cultivated land and in others growing nothing but furze and heather. Rodney-street was projected about 1780. It is a current tradition that it was first proposed to call the new street "Schlink-street," to perpetuate the name of a Dutchman who had purchased a considerable portion of land. The name, however, being very objectionable, as one that was suggestive of prematurely and newly born calves converted into veal, it was changed in 1782 to Rodney-street, the gallant Admiral Rodney having in that year defeated a fleet of French line-of-battle ships off Guadaloupe. This, no doubt, changed the destiny of the street, for there is a good deal in a name after all. We cannot imagine the great Dr. Parker Pepps living in Schlink-street, but "Dr. Parker Pepps of Rodney-street" impresses us at once as being according to the "eternal fitness of things" professional. In 1807 there were many portions of Rodney-street unbuilt upon on which grew heather and furze about the sandpits abounding in the vicinity. Dr. Gouldie, a celebrated physician of his time, lived in this street, as did Dr. Scott, the celebrated lecturer, and Dr. Brandreth. This was Dr. Brandreth the second, who married Miss Harper, one of "the lasses of Ashbourn," whose father, William Harper (one of the wealthiest men of his day and Mayor of Liverpool), never forgot to "toast" them at his own table. Old Dr. Brandreth lived in School-lane at one time, and in the year 1774, at 7, Church-street. Dr. Manifold, a highly esteemed physician, had a house in Rodney-street. Mr. Bickersteth, who dwelt near Mount Pleasant, was considered as skilful and dexterous in the conducting of an operation as Sir Astley Cooper. Thirty years ago that clever, kindly, dapper, but peppery little man, Dr. Seaton Smyth, lived in Rodney-street. Every other morning his coach-house in Roscoe-street, at the back, was filled with non-paying cancer and other patients; on other days they attended at the house in Rodney-street. The unpardonable sin which these people learned to avoid committing was treading on the pet dogs which surrounded the doctor. The doctor's carriage was generally drawn by cream-coloured ponies, which attracted considerable attention. The death of Dr. Seaton Smyth in the prime of life was a great loss to the poor of Liverpool.

To go back to an earlier period in the history of Rodney-street, mention must not be omitted of a personage who lived there and who played pranks on two or three Liverpudlian medical men. Allusion is made to Mr. D'Altera, or "little Joe," as he was called by his familiar friends. Joe was chairman of a celebrated society called the "Committee of Taste" or "Minions of the Moon," the members of which were fast young men who objected to the shape of their neighbour's knockers, signs, and so forth. Joe himself was one of the merriest, wittiest, and most thirsty souls in the town. The "Committee of Taste" carried on a long war with Mr. Parke, the famous surgeon, touching the shape of his knocker, which, in a fit of waggish displeasure, they had excommunicated. It was no light thing to cross these gentry, and though the surgeon kept putting up the knocker with commendable regularity and courage, the "Minions of the Moon" were equally diligent in wrenching it off. It is probable that the committee won in the end. Mr. Parke, when a very young man, attended in his professional capacity the French prisoners confined in the Tower in Water-street during the war with France which broke out in 1756. He was a man of great talents and extensive practice. In the year 1776 he went to reside in Basnett-street, which was then considered so much in the outskirts of the town that his friends thought him indiscreet in establishing himself in a situation where his patients would have to follow him to so great a distance. This fact alone speaks volumes for the marvellous development of Liverpool during the last 120 years. Mr. Joe D'Altera and his "Committee of Taste" once played a trick on Mr. William Wallace Currie, the eldest son and biographer of the great Dr. Currie, who wrote the life of Robert Burns. Mr. W. W. Currie was a notable man in his day, and filled the Mayoral Chair in Liverpool in 1836. He was not a man to take kindly to a practical joke; indeed, few people do, except the perpetrators. Imagine, then, the feelings of this grave and cultured namesake of Scotia's darling hero on his arrival at his office one morning when he saw his name on the door transformed into "William Wallace, Currier"! On another occasion the "Committee of Taste" fell foul of a certain Dr. Solomon, who then lived in a large house at the top of Low Hill. His grounds were studded over with statues, which he was not a little proud. They were voted to be not of classical by the committee, and the decree went forth for their removal and was carried out on the appointed night, when they were all taken from their pedestals, the "Old Charley" of the beat being either asleep or feed or frightened into silence. This Dr. Solomon was a remarkable character. He was the inventor and proprietor of the celebrated "Balm of Gilead." In 1816 he resided at the junction of Great Newton-street and Dansie-street, where the latter runs into Brownlow-hill. His house was at the corner of the street, his gardens extending into Brownlow-street. This part of the street was then called Solomon's place. From this place Dr. Solomon removed to Gilead House, Kensington, where he hospitably entertained his friends. He drove four horses in a dashing carriage. On one occasion he followed the coach of Lord Sefton (who was one of the most expert whips of his day) to Heywood's Bank, where the two vehicles pulled up together. Dr. Solomon in flourishing his long whip contrived to get the thong so inextricably entangled round his body that he was obliged to call his groom to assist him out of the predicament. On one occasion a guest, when the bottle had circulated freely, and "all went merry as a marriage bell," asked the doctor why he did not treat them to the celebrated "Balm of Gilead." Dr. Solomon replied that he should be happy to do so if those present wished it. The price of the "Balm" was a guinea a bottle. The party expressing a desire to taste the famous compound, half-a-dozen bottles were ordered in, which were duly consumed and highly relished. On the party breaking up each guest was favoured with a little bill of his share of the expense of the "Balm." On Dr. Solomon being taunted with wishing to make his company pay for their entertainment, he reminded those present that it was by the sale of his "Balm of Gilead" that he was able to treat them so hospitably and to make them welcome to his well-spread board. He therefore insisted upon being paid for his "Balm" as specified in the "bills delivered." When the fact oozed out Dr. Solomon's conduct was highly applauded, while the guests at the feast were heartily laughed at. Dr. Solomon once played a trick on a Custom House officer. The doctor, having shipped a case of "Balm of Gilead" to go abroad, the Custom House officer, finding the value declared so much below the usual selling price of the article, seized the package. On Dr. Solomon finding his "Balm" had been detained he became very wrath and determined on revenge. He thereupon sent another package to the docks for shipment, which was made up precisely like the former, with the same description of bottles, labels, and wrappers. These bottles, however, only contained common spirit, sugar, and water. Supposing that they contained the real stuff the man seized the package. Dr. Solomon refusing to release it, it was thrown on the officer's hands, who found afterwards to his cost of what the contents of the bottles consisted. Dr. Solomon chuckled gaily at the success of his scheme, declaring that he "vood teach dem to seize his goots." Dr. Solomon started Lord Sefton in the election of 1818. The flags were all painted at Gilead House, and cost at least £1000. Such a quantity of ribbons of his lordship's colours was given away by Dr. Solomon that there was one family in the town who had, many years after, quite a large stock remaining of what was then given to them. It is said that Dr. Solomon gave the land for the Wesleyan Chapel in Moss-street. A story is told of some medical students stealing a favourite broad-brimmed white hat belonging to Dr. Solomon, who, on the discovery of his loss, had the town placarded with savage bills offering a reward for the apprehension of the offenders. Dr. Solomon erected a mausoleum on the Mossley-hill Estate for the reception of his wife's and children's remains and for his own resting-place. It stood on a picturesque delf, and was for many years an object of remark. It is now entirely swept away.

"Dr. Solomon," says Sir James Picton in his "Memorials of Liverpool," "was for many years one of the institutions of Liverpool. Long before Holloway's Pills were heard of or Morrison had established his 'British College of Health,' Solomon's 'Balm of Gilead' had penetrated to the utmost

Hosted by Google

bounds of the habitable globe. The Doctor was a gentleman of the Hebrew nation, who commenced his medical career in a very modest way in Marybone, Tithebarn-street, some time before 1796. The precise period when the Balm of Gilead first diffused its soothing influences over the ills of humanity I cannot accurately determine, but by the end of the century it had become very popular. From Marybone Dr. Solomon removed to Brownlow-street about 1800. In 1804, wealth and reputation increasing, he built himself a noble mansion at Kensington Liverpool, and called it, 'Gilead House,' where he resided until his decease. Gilead House, or Dr. Solomon's as it was familiarly called, was for many years the first house in approaching Liverpool from the eastward and attracted great attention from the beauty of the grounds and the trim style in which they were kept. The Doctor died about 1819, and was interred in a mausoleum he had erected for himself on an estate belonging to him at Garston. Many years after his decease the estate was sold by his representatives, his remains removed to one of the cemeteries, and the mausoleum pulled down. Well might the philosopher of Norwich say, 'All was vanity, feeding the wind and folly. The Egyptian mummies, which time hath spared, avarice now consumeth. Mummy is become merchandise, Mizraim cures wounds, and Pharaoh is sold for balsams.'" Gilead House was dismantled, and the land sold for building about 1846. Professional men attending patients in the streets which take their names from the great legal dignitaries—Cottenham, Denman, Coleridge, Weightman, Patteson, Rolfe, Coltman, and Pollock—will be interested in knowing that they cover the land formerly occupied by Gilead House, and its trim parterres and close-shaven lawns, which in the old coaching days were grateful to the traveller's eye as a harbinger of home after a long and tedious journey.

During the political excitement of 1818 Dr. Solomon issued the following circular:—

"WORTHY FREEMAN AND DEAR SIR,—The honour of your attendance is earnestly requested at Gilead House on Thursday morning next, the 18th inst., to proceed with the full band of music and colours to the tally, when I shall have the honour personally to accompany you as the friend of Lord Sefton, and the rest of my honest set of staunch fellows, who are in my list of Freemen, to regain for yourselves and brave companions the blessings of real freedom.—I am, Sir, your most faithful, obliged, and very humble servant,

"Gilead House, June 16th, 1818." "S. SOLOMON, M.D.

In Mr. T. B. Browne's "Survey of the History of the Newspaper Press" it is stated that the first attempt to establish a daily newspaper out of London was originated by Dr. Solomon, the patentee of the well-known "Balm of Gilead." This was the *Mercantile Gazette and Liverpool and Manchester Daily Advertiser*, the first number of which appeared on Aug. 6th, 1803. The Doctor appears to have been imbued with an advertising spirit in advance of his time, and the demise of his interesting daily paper was probably due to toxical doses of the "Balm of Gilead" administered in the form of undiluted puffs. It is regrettable to find that this "truly great man" has been dismissed in the following irreverent and unbrotherly fashion by Dr. Robert Watt in the *Bibliotheca Britannica*: "Solomon, Samuel, M.D., a Jewish quack, notorious for his 'Cordial Balm of Gilead,' died about 1818. A Guide to Health, or advice to both sexes in nervous and consumptive complaints, scurvy, leprosy, and scrofula; also on a certain disease, seminal weakness, and a destructive habit (onanism) of a private nature, &c., &c. 56th edition. West Derby, dateless, 12mo, 3*s*. A thing of shreds and patches from the author's own advertisements and Aristotle's Master-piece."

In a house in Mount-pleasant, which in after years became the Eye and Ear Infirmary, but is now a laundry, dwelt Dr. James Carson after his removal from Ranelagh-place, where he had lived from about 1817 to 1830. He had a board put up near his late residence intimating the alteration of his whereabouts. Just at that time Dr. Carson was recommending the copious use of water to his dyspeptic patients at mealtimes and was insisting upon it that it was "a perfect cure" for that complaint. One night Dr. Carson's sign-board was removed and replaced on the following morning with the addition to the address of "Take Notice, opposite the Pump," referring to the pump in the street facing Dr. Carson's house. The trick caused a good deal of joking at Dr. Carson's expense. Dr. Carson was the author of "An Inquiry into the Causes of the Motion of the Blood, with Appendix," Liverpool, 1815, and "Physiological Essays," 1822.

In the middle house in Trinity-place, behind St. Anne's Church, in 1808 resided Mr. Charles Angus, a surgeon, or at least one who was in some way connected with the medical profession. With him lived a Miss Burns, his sister-in-law, who acted as his housekeeper and governess to his children. Mr. Angus was a widower and had been to sea. Miss Burns in the month of March of the above year was taken unwell, and it was suspected that she was *enceinte*. On March 23rd she remained in the breakfast-room all day, suffering from excessive thirst and vomiting. Mr. Angus sat up with Miss Burns the night of that day, watched over her the following day, and again tended her on the next night, allowing no one to share his task. On the 25th Miss Burns told the inmates of the house that she was much better, and expressed a wish to have some Madeira wine. A servant having been sent for some, on her return found Mr. Angus asleep in a chair and Miss Burns dead in the corner of the room. Mr. Angus was taken into custody charged with the murder of the young lady. He was tried for this alleged offence at Lancaster on Sept. 2nd before Sir Allan Chambre. Sergeant Cockle, with Messrs. Holroyd, Raine, and Clark, was for the prosecution, and Messrs. Topping, Scarlett (afterwards Lord Abinger), and Cross were for the prisoner. The evidence was most conflicting, but there was evidently no case against Mr. Angus, for it was proved that during the whole period of Miss Burns's sickness the door of her chamber was open, anybody could have access to it, that no sounds of pain were heard, no cries of any description, no dead child was found on the premises, no signs of childbirth were visible, and that Mr. Angus had never quitted the house for a minute while his sister-in-law was lying ill. It was conclusively proved that Miss Burns's death was attributable to internal disease, under which she had suddenly sunk. A verdict of "Not guilty" was recorded. After the trial a hot controversy arose on the medical features of the case, in which Dr. Carson took a prominent part. His evidence at the trial completely upset the testimony of the adverse witnesses, especially that of his medical brethren. Dr. Carson wrote an admirable and masterly vindication of his own evidence, which had been attacked. He hit his opponents heavily. It was endeavoured to show that Miss Burns's death arose from an attempt to procure abortion. Mr. Angus frequently declared that he loved and respected Miss Burns too well to do her any harm. The case created immense excitement at the time, not only in Liverpool, but throughout the kingdom, especially amongst the medical profession.

Gleave-street, Everton, takes its name from Dr. Gleave, an Everton physician. On the south of Gleave-street stood the once-famous "Half Way House," which, having been converted into a cake-shop after it lost its licence, was purchased by Dr. Gleave, who erected a mansion on it. The garden adjoined the residence of the Rev. Archdeacon Brooks, senior rector of Liverpool, who, on being asked whether the necropolis which adjoined his garden was not detrimental to his health and comfort, replied "No; he had always found the inhabitants very quiet neighbours."

Some curious entries occur in the town records of Everton, as, for instance, "Paid Dr. Livesley for setting Alice Knowles' leg, 42*s*."; "Paid for a coffin for Witch Nancy's child, 1*s*. 6*d*." The little Baptists' burying-ground, now covered by the Fabius Chapel, in Everton-road, is named after "Dr." Fabius, who, about the year 1698, was a pious young apothecary named Bean, living in Low-hill. He Latinised his name to Fabius from Faber. His family gave the cemetery to the Baptists "for ever" in 1707, and "Dr. Fabius" himself was laid to rest therein, the inscription on his tombstone being: "In this dormitory reposeth the body of Daniel Fabeus, who departed this life ye 12 April, 1718, aged 37."

"A singular physiological problem kept the Liverpool public on the *qui vive* during the autumn of 1817," says Picton in his "Memorials of Liverpool." "A Miss M'Avoy, a young lady residing in St. Paul's-square, about seventeen years of age, was attacked by hydrocephalus and partial paralysis. Her eyes were affected by gutta serena, and she was pronounced by her medical attendants to be entirely blind. Shortly afterwards she was reported to possess the faculty of reading print and distinguishing colours by the touch, her eyes being so completely bandaged as to prevent the possibility of deception. The story got wind, and the house in St. Paul's-square became a centre of attraction to the wonder-loving public. There could be no mercenary object to gain by imposture, as the family were respectable and no money was ever received. Many wonderful accounts were published of

Hosted by Google

her capacity of deciphering the smallest print and the most delicate colours in utter darkness as well as with the eyes covered. Dr. Renwick, a physician of eminence published a pamphet, in which he gave explicit credence to the new and supernatural faculty. Encouraged in this way, her pretensions assumed a higher flight. She now claimed the faculty of discerning objects at a distance by placing her fingers behind her upon the glass of the windows and was said in this way to have described the figures of persons in the churchyard opposite and the colour of their clothes. This naturally excited some suspicion, which was strengthened by other circumstances. The interposition of any substance between her face and hands deprived her of the faculty of seeing as it were by touch. This she attributed to the necessity for her breath having free and uninterrupted communication with her hands. To obviate this difficulty an ingenious gentleman (Mr. Egerton Smith) contrived a mask which whilst entirely covering the eyes and face, left the breathing free and uninterrupted, and offered to pay twenty guineas, which another gentleman doubled, if Miss M'Avoy, with this mask on, could read a single line of moderately sized print. After some equivocation the test was declined, and Miss M'Avoy's pretensions fell to zero and were soon forgotten. There is nothing new under the sun. The brothers Davenport of more recent days and the modern spiritualists with their mediums are uniformly found to fail when, as in this instance, brought to the crucial test of practical experiment and common sense."

Among the items in the accounts of Mr. Churchwarden Dennison of Liverpool for the year 1818 were £32 15*s.* 6*d.* for mourning and scarves for the parish officers attending the funeral of the parish practitioner and £11 0*s.* 6*d.* for six gold-laced hats for the constables. He was an ideal churchwarden from a workhouse point of view, his hospitality (at the parish expense) being almost unbounded. There were weekly dinners at the workhouse on Tuesdays, to which his friends were very freely invited. Sixteen dozen of port at 65*s.*, £70 worth of Vidonia, and sixteen gallons of rum had thus been consumed in the year, besides brandy, jellies, and lemons; 200 gallons of wine were given to the clergy for their private use. £1416 were paid for wine, spirits, and malt liquor within the year; and yet this liberal soul, who displayed such respect for the parish doctor, clergy, and his own friends, had his generous outlay disallowed by the quarter sessions, and in the end had to pay about £2000 for his short but glorious reign as churchwarden.

In a list of the officers who commanded the several regiments or companies raised in Liverpool for the defence of the country during the threatened invasion in 1803 are found the names of Joseph Brandreth, gentleman, who was surgeon, and James Dawson, gentleman, who was assistant surgeon, in the 1st Battalion of Liverpool Volunteers, raised at the expense of and commanded by Lieutenant-Colonel Bolton; Henry Parke, gentleman, was surgeon in the Liverpool Volunteer Artillery, commanded by Peter Whitfield Brancker; and George Catlow was surgeon of the Liverpool Independent Rifle Corps.

Dr. Peter Crompton, of Eaton House, was one of the prominent reformers and political orators of Liverpool. He came of an old Lancashire family, of which a branch was settled in Derbyshire. At the election of 1820 the Whigs in Liverpool were sadly at a loss for a candidate. Eventually Dr. Crompton and Mr. Leyland were nominated against Mr. Canning and General Gascoyne, but the contest was hopeless from the first. At the close of a seven day's poll the numbers stood: Canning, 1635; Gascoyne, 1552; Crompton, 345; Leyland, 125. Dr. Crompton was one of the class preferred by Cæsar—

> "Let me have men about me that are fat,
> Sleek-headed men, and such as sleep o' nights."

His jolly, rotund person was the incarnation of good humour, while his proposer and principal supporter, Colonel Williams, was lean, wiry, and of sour temperament. It may be surmised that the merciless wit of Canning played like lightning around such a pair. The doctor was not long before he "put his foot in it." Speaking on the hustings after his nomination he said: "A rumour has been spread abroad that my opposition to the return of our late representatives is wholly vexatious. Fool, indeed, should I be to come forward and put myself to every inconvenience in a place where I live to such a purpose; and still greater fool to expose myself thereby to the severe censures of Mr. Canning whose exquisite wit and humour can turn into ridicule everything, both sacred and human. The impartial page of history informs us that Nero fiddled while Rome burned. Mr. Canning smiled when Colonel Williams flashed his crimes in his face." The Mayor, having requested the worthy doctor not to indulge in personalities, the candidate continued:—"I thank you, Mr. Mayor, for the offer of your protection, but I fear not the face of man. I was observing, when I was interrupted, that while Rome fiddled Nero burned. (Laughter). I meant to say, that while Rome burned Nero fiddled. But I cannot smile amidst the ruins of my country, &c., &c." To this Mr. Canning replied at the close of his speech as follows:—"The honourable doctor, indeed, has tempted me somewhat high with his references to ancient history—with his allusion to the conflagration of Rome and to the Emperor Nero's musical accomplishments. Of that allusion I have not, to this moment, made out the application; but if he intended (which seems the most probable solution of it) to compare the honourable colonel's eloquence to a conflagration, and his own to a musical instrument, I have only to hope that if I offended by smiling at the colonel's fire, I may have made atonement by looking grave at the doctor's fiddling." Dr. Crompton was partner in a brewery. This, and the fact that his nomination had been decided by one of the five brothers Harvey, two of whom were brewers, gave point to the following squib:—

> "And when the doctor's sour ale's done—
> Ah! Cunning Doctor!
> He will laugh at his foes who have made his tap run,
> And the Harveys will join in the excellent fun,
> With their brewing, mixing
> Nutgall and treacle—
> Ah! Cunning Doctor!"

Dr. Crompton died Jan. 23rd, 1833, aged sixty-eight, leaving five sons and three daughters. Charles, the second son, was raised to the Bench as one of the puisne Justices of the Common Pleas. One of his daughters married the Rev. Llewellyn Davies, formerly Rector of Christ Church, Marylebone, another married Mr. R. Hutton, some time M. P. for Dublin. According to the Rev James Aspinall, M.A., who knew him, Dr. Cromptom was "a fearless, outspoken man, English all over in his bearing." He was the author of "A Letter to Robert Townley Parker, Esq., High Sheriff of the County Palatine of Lancaster," published in 1817.

During the progress of the election it had been announced that Colonel Williams was to stand for the representation of the county, to be proposed by Dr. Crompton. In his closing speech, after his election and chairing, Mr. Canning thus alludes to the circumstance: "It was surely no small presumption, especially on the part of those who are continually declaiming against the undue interference of powerful individuals and against the servile surrender of the freedom of election, it was no small presumption, I say, for any such party to think that they might with one hand grasp the representation of Liverpool and with the other indicate the representative of the county. Gentlemen, the process by which this twofold operation was to be brought about was one of a curious kind. It reminds me of what I have read in some of the political pamphlets of, I believe, the reign of Queen Anne, of an empiric who, not liking to sound his own praises but wishing to have them sounded, hit upon a notable expedient of obtaining the benefit without incurring the reproach of such a proclamation. A youth preceded him in the crowd crying with a loud voice, 'My father cures all sorts of diseases.' The doctor marched behind him with a sedate and solemn step, simply declaring, 'The youth says true.' Now, Colonel Williams appears to have acted on our hustings the part of the ingenuous youth when he proposed Dr. Crompton to you as a healer of all the diseases of the political Constitution. Dr. Crompton followed with a modest and measured pace, not singing his own praises, but admitting the truth of the praises which had been sung. But one good turn deserves another, and the operation in hand was, as I have described it, twofold. The peculiar inducement held out to you to receive Dr. Crompton as your representative was, that he was in possession of some great specific which would enable him to restore peace to the community and to heal the differences by which the nation is unfortunately distracted. What this panacea was we could never extract from the doctor on the hustings. Thus much only could we learn, that it was some cabalistic name which he was to pronounce upon the hustings at Lancaster which would still the popular storm and diffuse

Hosted by Google

liberty and contentment throughout the country. Well, when the time arrived, and Dr. Crompton departed for Lancaster, we found that the scene exhibited a few days before at Liverpool was to be acted over again at the county town, with a change only in the order of the *dramatis personæ*. Dr. Crompton was now to be the herald of the praises of his proposer; and the name of Williams, pronounced in the shire-hall, was the charm by which the county was to be lulled into peace and exalted into glory. Colonel Williams's election for the county was the prescription by which all diseases were to be healed. Pity that the county should reject the dose; but natural enough that after that rejection, you should upon his return to you reject the doctor."

This was not the first time that Canning's wit had been pointed with medical similes. In his youth he had lampooned Lord Sidmouth (then Mr. Addington), who commonly went under the sobriquet of "the Doctor," in the following parody:—

"My name's the Doctor; on the Berkshire hills
My father purged his patients—a wise man,
Whose constant care was to increase his store,
And keep his eldest son—myself—at home.
But I had heard of politics, and longed
To sit within the Commons House, and get
A place; and luck gave what my sire denied.
Some thirteen years ago, or ere my fingers
Had learned to mix a potion, or to bleed,
I flatter'd Pitt; I cringed, and sneaked, and fawned,
And thus became the Speaker. I alone,
With pompous gait, and peruke full of wisdom,
Th' unruly members could control, or call
The House to order.
Tir'd of the Chair, I sought a bolder flight,
And grasping at his power, I struck my friend,
Who held that place that now I've made my own.
Proud of my triumph, I disdained to court
The Patron hand which fed me—or to seem
Grateful to him who raised me into notice.
And when the King had called his Parliament,
To meet him here convened in Westminster,
With all my family crowding at my heels,
My brothers, cousins, followers, and my son,
I showed myself *Prime Doctor* to the country.
My end's attained, my only aim has been
To keep my place—and gild my humble name."

Opposite the top of St. John's-lane there was at one time a capacious stall for the sale of herbs and quack medicines, the proprietors of which were Messrs. Startup and Brown, one of whom sold the drugs, while the other, dressed in a "mortar-board" cap and a stuff gown, delivered short lectures to the gaping crowds which assembled in front of the stall on the *medicamina artis*.

In 1826 a horrible disclosure took place connected with Hope-street, Liverpool, that filled the minds of the people with horror. One morning in October three barrels were carted to the pier and shipped on board the Glasgow packet as "salted hides." The captain of the packet and some of the passengers soon noticed that a disagreeable odour prevailed in the vicinity of these casks and then, as the novelists say, "a strange thing happened." The passengers, insisting upon the barrels being put on shore, in the act of doing so one of them burst open, when a human body was found closely packed in it in salt. In the other two were similar "salted hides." The carter who conveyed them to the vessel having been discovered the police were communicated with, by whom it was found that the barrels had been brought from a house in Hope-street, which on being searched was found to contain no less than thirty-three other corpses regularly salted and cured. The bodies had been taken from the parish cemetery in Cambridge-street. These subjects had been obtained for the use of medical schools, with which, it appeared, a regular trade was carried on.

One of the houses which now forms part of the East Dispensary, in Richmond-row, Liverpool, was once the scene of a laughable incident. The late Robert Crompton, watchmaker, poet, and journalist, happened to be passing one day when he heard groans and uncharitable sounds issuing from the house in question. He turned in to investigate the cause and to render assistance, if necessary. To his surprise he found an immense canvas lying on the floor, or rather tossing upon it like a vessel in distress on the angry sea, and sounds of blasphemy came up as it were from some Jonah down below. On raising the canvas, he discovered the late William Daniels, a famous local artist, lying on the floor in a very inartistic and anti-temperance condition, but able to swear most fluently. Daniels, a man of fine thirst, had been painting a large picture of Shylock, and, of course, solacing himself as usual with the flowing bowl. Then Shylock, acting up to his mean and vindictive record, had taken advantage of the artist's condition and fallen upon him, so that he was unable to rise or extricate himself without assistance.

De Quincey, the opium-eater, lodged for some time in Everton-terrace, in a little cottage to which access was obtained through a wicket and by two stone steps. During his stay in Liverpool he was in some way connected with the firm of Meritt and Wright, booksellers, Castle-street, who published in 1769 a book entitled "Liverpool Testimonial to the Departed Genius of Robert Burns, the Scottish Bard." The name of Dr. Currie (who published, according to Charles Lamb, a very silly biography of the poet) is amongst the subscribers, and Dr. Solomon and Dr. McCartney have their names down for different sums. The list of subscribers to the work is introduced by the following paragraph: "We whose names are hereunto subscribed, calling to mind the delight we have received from the immortal works of this great but unfortunate genius, offer the sums affixed after our names towards the support of his family, as a proof of the sympathy we feel in the affliction of the living, and of the honour we pay to the memory of the dead." Dr. McCartney was a celebrated Roman Catholic physician who had a large practice in Liverpool. He resided in Mount Pleasant, a thoroughfare made famous as the birthplace of William Roscoe. Dr. McCartney's house was afterwards occupied by Mr. James Dawson, who, on giving up practice, went to reside at Wray Castle, by Windermere Lake. Mr. Dawson was President of the Medical Institution in 1847, and one of the consulting surgeons to the infirmary.

At 115, Mount Pleasant resided Mr. Hugh Neill, the originator of the Eye and Ear Infirmary, then located in Harford-street, Mount Pleasant.

Dr. George Churchill Watson, of 4, Bedford-street North, a physician who practised in Liverpool about half a century ago, was the writer of some admirable letters on sanitary reform in the *Liverpool Standard*. These letters, signed "Medicus," were, in fact, the pioneers of that great movement in that town. The eccentric Joseph Williamson, who had a mania for excavations, and whose tremendous underground works at Edge Hill were declared by Robert Stevenson to be marvels of construction, once, through the intercession of one of his tenants, gave an order to inspect his works to Dr. Watson. The order ran thus: "Dr. Watson is not to be interrupted in his walks on my premises, either on the surface or under the surface. J. W., E. H. January, 1839." Dr. Watson's account of the works when they were in their prime was that they were perfect marvels, not only for their great extent but for the excellence of their construction and their inapplicability to any possible purpose. It was no small honour to be allowed to see these extraordinary works, as Williamson seemed jealous that other people should be gratified by a sight of them. It has been conjectured that he spent at least £100,000 upon them. When the tunnel was in formation from Edge Hill to Lime-street about 1834, and was passing through and under his property, Mr. Williamson actually drove a tunnel under the railway tunnel, appearing himself in the aperture made, to the amazement of the navvies, who were told that if "they wanted to know how to tunnel he could give them a lesson in that polite art."

THE PRINCE OF WALES AT GUY'S HOSPITAL.

THE OPENING OF THE NEW SCHOOL BUILDINGS.

ON Wednesday afternoon last H.R.H. the Prince of Wales, accompanied by the Duke of Cambridge, attended at Guy's Hospital to open the new medical school buildings, which have been erected at the cost of the staff of the school, and have entailed an expense of £12,000. The present buildings, moreover, are only an instalment, as it is contemplated to rebuild the whole medical school, for which purpose it is estimated that a further sum of £35,000 will be required. The buildings now opened provide an admirably arranged lecture theatre, together with two large laboratories for practical instruction in histology and physiological chemistry.

The Prince of Wales on arrival was received by Mr. Cosmo Bonsor, M.P., the treasurer of the hospital, and Dr. Perry,

Hosted by Google

the superintendent of the medical school, and proceeded to the board-room, where he presided over a short meeting of the general court. After the members of the medical and surgical staff had been presented to His Royal Highness a financial statement was made by Mr. Bonsor showing that the total sum received up to this date in answer to the Prince's appeal for a re-endowment fund of the hospital had amounted to £194,000.

An address of welcome was then read by Mr. Howse, the senior surgeon, when the Prince proceeded to the hospital, where Dr. Pye-Smith, the senior physician, described the objects of the building and asked his Royal Highness to declare the building open. After referring to the position of the voluntary hospitals in England, and the development during the present century of the influence of the medical schools and scientific teaching, Dr. Pye-Smith went on to point out how their development must be assisted by corresponding increase of facilities for study. But the school and the hospital were separate institutions, and the school could not, of course, obtain any of the money subscribed for the hospital. In the absence of Government grants or private beneficence the staff had, therefore, only one resource to maintain their school at the proper level, and this was to find the money for themselves.

The Prince of Wales then declared the building open, and delivered a short address in which he spoke of the immense services to the community that were performed by laboratories in which the laws of life were investigated. He spoke of the heritage which the Guy's student had in the examples of such men as Astley Cooper, Bright, Addison, Hodgkin, and Gull, and laid particular stress upon the gentle and humane spirit which, not confined to any one school, is the best possession of the medical faculty. He stated, amidst cheers, that after careful inquiry he had satisfied himself *that whenever experiments upon animals were performed in the school of Guy's Hospital they were undertaken with the object of promoting advances in medicine or surgery which are likely to be of benefit to suffering humanity, and that such experiments were conducted under strict supervision by highly qualified investigators, while in practice the only operations performed upon animals not in a condition of complete anæsthesia were inoculations and hypodermic injections.* Finally, addressing the students, he exhorted them to take care that "the great profession to which you aspire to belong shall, when you leave it, stand as high in the service and in the affection of the public as it does at the present time."

The Prince of Wales's words were received, as might be expected, with the utmost enthusiasm, and all references in the speech of Dr. Pye-Smith to the aid that he had given to the endowment fund by placing himself at its head were loudly cheered, as were allusions to the Jubilee Fund for London Hospitals. Afterwards His Royal Highness re-named one of the wards, which has just been re-opened, "the Queen Victoria Ward." Subsequently tea was served to the visitors, who must have numbered over 2000, and at the end of the afternoon the prizes and medals were distributed to the successful students in the medical school by Mrs. Cosmo Bonsor.

BANQUET TO LORD LISTER BY HIS FORMER HOUSE SURGEONS AND DRESSERS.

AMONG all the manifestations of the profound satisfaction felt by every member of the medical profession at the recognition of the work of Joseph Lister shown by his elevation to the peerage by Her Majesty, none can have given such pleasure to himself as the unique gathering of thirty of his old house surgeons and over a hundred of his old dressers, who assembled on Wednesday, May 26th, at a banquet in his honour at the Café Royal. It is said that no man is a hero to his valet; it is certain that no man is surrounded by more candid and acute critics in the shape of house surgeons and dressers than a surgeon in a teaching school, and to secure and retain the affection, as well as the unqualified admiration, of those who have been most intimately associated with him is the happiest lot that can befall any man who has strenuously tried not only to advance his art, but to inspire those who shall come after him with high aims and with correct principles for practice. The gathering on Wednesday proved that Lord Lister had succeeded in both these directions. It is unnecessary to repeat what has so often been said of the far-reaching effects in saving life and diminishing suffering that have resulted from the application of Listerian principles to the every-day practice of surgery. But the speeches showed how successful he had been in exerting on his pupils a personal influence in setting before them a high ideal, insisting on minute conscientious care and humane consideration in the management of every case that was intrusted to their care. The result of his teaching was shown by the eminence to which many of those present had already arrived. Among the old pupils who had assembled to entertain him were Professor Coats, Dr. Sims Woodhead, Mr. Watson Cheyne, Mr. Francis Caird, Dr. Dundas Grant, Dr. Beatson, Sir Hugh Beevor, Dr. T. F. Chavasse, Dr. G. A. Gibson, Dr. D. Burgh Birch, Dr. Heron, Mr. Cheatle, and Dr. St. Clair Thomson.

The usual loyal toasts having been duly honoured Dr. Hector Cameron proposed the toast of "The Army, Navy, and Reserve Forces," referring particularly to the death of Surgeon Fyfe, R.N., in the Benin Expedition, who was shot through the heart while giving assistance to a wounded comrade, "dying the death of a soldier while doing the work of a surgeon," and the toast was responded to by Surgeon Thorpe, R.N., and Brigade-Surgeon-Lieutenant-Colonel Allin.

Dr. Hamilton Ramsay, as the oldest living house surgeon to Lord Lister, then presented the following address:—

To the Right Honourable Lord Lister, Surgeon Extraordinary to the Queen, Emeritus Professor of Clinical Surgery at King's College, London; late Regius Professor of Clinical Surgery in the University of Glasgow, and Regius Professor of Clinical Surgery in the University of Edinburgh.

MY LORD,—We have had the great honour and privilege of serving under your Lordship as House Surgeons, Clerks, or Dressers, and we beg leave to offer you on this occasion of your elevation to the peerage our affectionate and respectful congratulations. This memorable year of a memorable reign will to all of us be ever associated with the public recognition of your splendid work.

To you, our revered master, we can never adequately express our indebtedness for all you have taught us and for the example you have been to us. We beg leave to hand you the list of those who have had the honour of being intimately associated with your Lordship in the great work by which you have made possible the triumphs of modern surgery, and on behalf of those who have been prevented from joining us this evening we beg to subscribe ourselves your very grateful and affectionate pupils.

Signed by { JOSEPH COATS, Chairman, ST. CLAIR THOMSON, Honorary Secretary, and all the company present.

Lord Lister, in responding, spoke of the intense gratification which this spontaneous demonstration of his old pupils had given him and said that he was specially glad that the album, which he should prize highly, should have been presented by Dr. Ramsay, who was not only one of his first house surgeons, but had previously been a student of his in the extra-mural school of Edinburgh, and mentioned that Dr. Ramsay was first attracted to the study of medicine from charitably attending cases of cholera during an epidemic in a mining district.

Mr. London, an old King's College student, presented an address from the medical practitioners of British Guiana, which was suitably acknowledged.

Professor Coats, in proposing the toast of the evening in an admirable speech, said that they had not only to congratulate Lord Lister on his elevation to the peerage, but on the world-wide acceptance of the principles of antiseptic surgery which he had laid down. Even before Lord Lister had introduced antiseptic methods into surgery he had by his physiological and pathological work shown extraordinary capacity, as those who had worked with him at Glasgow would well remember People often spoke of Listerian antiseptics as if various forms of apparatus, instead of certain fundamental principles, were the essentials. Lord Lister, however, while adhering inflexibly to the principles, had always been ready to adopt new methods or to discard apparatus if he thought that asepsis could be as well or better secured by so doing, and the system had not only survived, but had been triumphant, modifying the whole modern practice of surgery. But, above all, it was the personal charm of Lord Lister which endeared him to those who worked under him, his high ideals of work, his humanity to his patients, and his gentle consideration for his juniors.

Lord Lister, in rising to reply, was greeted with long-continued cheering, and was evidently much moved by the

Hosted by Google

warmth of his reception. He said he was touched profoundly to find that the affectionate loyalty which those who had worked under him had always shown him should have persisted for so long a time. The kind words which had been said and the way in which they had been received would always remain with him as indications that his labours had not been altogether in vain.

Dr. St. Clair Thomson said that he had received "hundreds" of letters from old pupils who were unable to attend. One of them (Dr. Aikman, of Guernsey) had sent the flowers with which the room was decorated.

A pleasant incident, showing that the feeling of the present generation is no whit behind that of their predecessors, was the receipt of a telegram from the house surgeons and house physicians of the Edinburgh Royal Infirmary conveying their congratulations.

The committee and Dr. Elder and Dr. St. Clair Thomson (the honorary secretaries) are to be congratulated on the success of this banquet, which will never be forgotten by those who were fortunate enough to be present.

THE FIRST ANNUAL DINNER OF THE INDIAN MEDICAL SERVICE.

THURSDAY, May 20th, saw the inauguration of a new and highly interesting medical dinner at the Café Monico, when the members past and present of the Indian Medical Staff dined together for the first time. The chair was taken by the man who was marked out at once by every imaginable claim for the post, Sir Joseph Fayrer, and he was supported by the Secretary of State for India, Lord George Hamilton. The occasion was in every way successful. Upwards of seventy gentlemen sat down to dinner, among whom we may mention Sir Trevor Lawrence, Sir Joseph Ewart, Dr. Playfair, Surgeon-Generals W. R. Rice, C.S.I., J. Cuningham, C.S.I., P. W. Sutherland, De Renzy, Hooper, and Colvin Smith; Deputy-Surgeon-Generals Kilkelly, McKellar, Farquhar, Raddock, and Cayley; Surgeon-Colonels Costello, Porter, G. S. Sutherland, Richardson, Roberts, Riddell, Harris, and Cates; Surgeon-Lieutenant-Colonels Holmes, Massy, Bate, Lyon, C.I.E., Eyre, Baker, Scully, Wright, Reid, Williams, Skardon, Griffiths, and Freyer (hon. sec.); Brigade-Surgeon-Lieutenant-Colonels Aitchison, Johnson, and Macleod; and Surgeon-Major Sir G. S. Robertson, K.C.S.I.; and the following guests: Lord George Hamilton, Sir William MacCormac, President of the Royal College of Surgeons of England, Sir J. Dick, K.C.B., Director-General, R.N., Surgeon-General Jameson, Director-General of the Army Medical Staff, Dr. Dickinson, President of the Royal Medical and Chirurgical Society, Mr. Reginald Harrison, President of the Medical Society, Mr. Richmond Ritchie, and Dr. S. Squire Sprigge.

Sir Joseph Fayrer made an excellent chairman, and his speech in reply to the toast of the evening, proposed by Sir William MacCormac, was full of interest for all his hearers. He showed that the pride of the members of the Indian Medical Service in their department was justifiable, inasmuch as British rule over the brightest jewel of Her Majesty's Crown might without exaggeration be considered to have had its origin in certain concessions made by the Emperor of Delhi to Gabriel Broughton, surgeon of the East India Company's ship *Hopewell*. Sir Joseph Fayrer then went on to mention the names, and in some cases the exploits, of the great men, past and present, of the Indian Medical Service in the three important and widely varying sections into which their work falls, linking the names of Hamilton and MacNeil, Falconer and Cleghorn, Keegan and Freyer, Cayley and Robertson, and many others, into one chain of scientific, administrative, and military performance.

Lord George Hamilton responded for the guests in a sympathetic and thoughtful speech. Referring to the triple trouble of cholera, plague, and famine with which our Indian Empire has been sorely tried, he had words only of the highest praise for the officers of the Indian Medical Service, upon whom so much anxious and dangerous work has fallen in consequence. He referred with emphasis to the fearless and unselfish conduct that went hand in hand in the service with medical skill, and "brought down the house" by a statement that he considered a dispensary established on the way to Chitral to be of more efficacy in the maintenance of peace than a regiment of soldiers would be.

Surgeon-Lieutenant-Colonel Freyer, upon whom the organisation of the dinner devolved, is to be congratulated on the results of his efforts. A successful *réunion* was made doubly pleasant to all by the presence and the appreciative words of the Secretary of State for India.

HOSPITAL REFORM ASSOCIATION.

A MEETING of the Hospital Reform Association was held on Wednesday afternoon last in the Victoria Hotel, Manchester. The chair was occupied by Mr. Walter Whitehead, who explained the reasons of the society's existence. Mr. T. Garrett Horder, the secretary of the Association, mentioned that it had been said twenty-two years ago that, as far as Manchester and Salford were concerned, the oft-heard cry of the abuse of medical charities was a thing of the past. It was for them to say whether this was still true. From what he had gathered in looking over the returns of the Manchester medical charities he was disposed to say they were very much abused indeed, and that the present system of investigation did not really do much towards preventing the abuse.—The Chairman then moved: "That in the opinion of this meeting the time has arrived when an inquiry should be made into the mode of administering medical relief in the Manchester and Salford hospitals and dispensaries; and it is further of opinion that such an inquiry should be conducted by a committee which should be representative of all the interests concerned."—Dr. Worswick seconded the resolution.—After the resolution was adopted the following committee was appointed: Mr. Walter Whitehead, Mr. G. A. Wright, Mr. C. Behrens, Dr. Alexander Stuart, Dr. S. Woodcock, Dr. A. Godson, Mr. F. Scott, Dr. T. Harris, Dr. W. J. Sinclair, Dr. Lloyd Roberts, and Dr. Vipont Brown (hon. sec.).

The meeting ended with the customary compliments to the chairman.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria at Hatley Cockayne.—The story told by Dr. G. S. Buchanan, as to diphtheria in the little village of Hatley Cockayne, in the Biggleswade rural district of Bedfordshire, is typical of an occurrence of that disease in rural areas. When investigation came to be made and obscure attacks could be interpreted in the light of subsequent events, it was found that sore-throat of an infectious character commenced in the village in June, 1896, but even when a fatal attack took place owing to laryngeal complications it was at first assumed that the malady which was being dealt with was a form of follicular tonsillitis. But suspicion being roused a more careful examination was made towards the end of July, and it was discovered that there were then eleven attacks of diphtheria. The village consisted of four detached houses, including the rectory and two outlying farms, and fifteen cottages. In all but one of these latter, in which there were children, diphtheria occurred, twenty-three attacks of sore-throat of differing degrees of severity taking place out of sixty-four residents in the cottages in question. A number of these cases were severe, in so far at least as sequelæ were concerned, some of the post-diphtherial paralysis being grave and even fatal. The beginnings of the disease seemed lost in the earlier mild and unrecognised attacks; but the diffusion of the malady was in large measure due to personal infection contracted during either work or play; and in this connexion it is noted that the day school and the Sunday school were both held in a single small room attached to one of the cottages. Unfortunately no isolation was attempted. It is stated that the hospital belonging to the rural district was being reserved for cases of enteric fever, which was at the time prevalent in the village of Moggerhanger. We hope

Hosted by Google

this does not mean that the hospital is so contrived that cases of only one disease can be admitted at the same time; all such isolation hospitals, however small, should be designed on the assumption that at least two diseases in both sexes may be expected at any time. The concluding portion of Dr. Buchanan's report deals with the question of the water-supply of the village of Moggerhanger and also of Chalton, in both of which enteric fever had occurred. The wells seem to be fed by surface water which percolates through layers of glacial drift overlying the Oxford clay. This latter formation is one which presents considerable difficulties in connexion with water-supply; but this is no excuse for surrounding wells sunk in a surface soil with privies, cesspools, &c., in such a manner as to foul that soil. Dr. Buchanan incidentally gives a warning against any trust being placed in the "cleansing" of such wells. Where the fault lies in the fact that the surface soil through which the water flows is fouled by filth it is difficult to conceive how any one of intelligence can place reliance on the scraping and lime-whiting of the brickwork with which the well is lined. The process savours a good deal of that which is known as whitening the sepulchre.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Folkestone Urban District.—Two separate outbreaks of enteric fever occurred in Folkestone during 1896 as the result of the pollution of milk outside the borough boundary. In one instance the outbreak was due to a contaminated water supply and in the second no direct evidence of contamination could be detected. Mr. Yunge-Bateman insists that these two outbreaks furnish an admirable illustration of the manner in which one district is at the mercy of another, and he points out that it is only when illness has actually occurred as the result of a contaminated milk supply that the operations of the Infectious Diseases Prevention Act can be brought into play. Mr. Yunge-Bateman considers that a town should have the same control over dairies situated outside the borough, and which supply the town with milk, as it has over dairies within its limits.

Bournemouth Urban District.—Mr. P. W. G. Nunn reports that during 1896 there occurred at Bournemouth a case of small-pox which he thinks was not improbably contracted from a Gloucester mail bag. The patient was accustomed to handle mail bags from the infected town, and his attack occurred at a time which was consistent with this view. Mr. Nunn brought the matter to the notice of the postal authorities, and steps were taken to guard against any further introduction of infection from the suspected quarter.

Crewe Urban District.—Mr. Herbert Jones reports that the death-rate among illegitimate children in Crewe was during 1896 slightly lower than among children born in wedlock—a fact which forms an interesting exception to the general rule of a high mortality amongst illegitimate offspring. Arrangements have been made by the Crewe sanitary authority for the bacteriological examination of suspicious cases of diphtheria, and it has been decided to pay the notification fee, whether the result of the examination be positive or negative. Infantile diarrhœa is, it appears, always high in Crewe, and Mr. Jones has ascertained that incidence of the disease is highest in a certain area largely supplied with cesspools and privies. We must congratulate Crewe upon having at last adopted the Notification Act, as we have on other occasions had to express our disapproval of the attitude of the Crewe town council in this particular. Mr. Jones is, we believe, leaving Crewe for a wider field of activity, and it must be gratifying to him to feel that his successor will find the district now provided with notification and with isolation accommodation.

Stoke Newington Sanitary District.—The corrected death-rate of this district for 1896 was the lowest of the districts in the metropolis, being but 13·3 per 1000, as compared with 13·4 for Hampstead, which was the next lowest on the list. In discussing the question of isolation accommodation in the metropolis Dr. H. Kenwood doubts whether the Metropolitan Asylums Board will ever be able to provide accommodation for periods of exceptional prevalence of the disease, and he remarks that a scheme which would provide for this would necessitate a very large number of beds and persons remaining idle for many months in the year. The vestry of Stoke Newington has, we note, decided to supply the medical practitioners of their district with diphtheria antitoxin at cost price, and we can well understand that this provision will be highly appreciated. Dr. Kenwood regards it as a great waste of public funds that such a large amount should be expended on the purification of London water, and that it should afterwards be used so largely for flushing purposes. He rightly considers that sea water should be supplied to London for flushing and other purposes.

Cannock Rural District.—Dr. William Hosegood suggests that as a means of reducing the high infantile mortality of the district the county council of Staffordshire might arrange for a house-to-house distribution of leaflets setting forth in plain language the proper way of feeding babies, and drawing attention to the harm which is likely to result from improper food. Doubtless this measure would do some good—that is, if the parents could be persuaded to read the leaflets. We presume, however, that Dr. Hosegood would advocate that visits should be made more especially to houses from which births had been registered, and that the distributor of the leaflets should be capable of demonstrating to the parents the principles inculcated in the leaflets.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6119 births and 3617 deaths were registered during the week ending May 22nd. The annual rate of mortality in these towns, which had declined in the four preceding weeks from 18·8 to 16·5 per 1000, rose again last week to 17·2. In London the rate was 15·4 per 1000, while it averaged 18·3 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·9 in Croydon, 13·1 in Leicester and in Bradford, 13·7 in West Ham, and 14·0 in Swansea; the highest rates were 22·0 in Manchester, 22·1 in Burnley, 22·4 in Plymouth, and 23·3 in Liverpool. The 3617 deaths in these towns included 357 which were referred to the principal zymotic diseases, against 315 and 340 in the two preceding weeks; of these, 102 resulted from whooping-cough, 97 from measles, 43 from diarrhœa, 42 from diphtheria, 38 from scarlet fever, 34 from "fever" (principally enteric), and 1 from small-pox. No death from any of these diseases was recorded last week in Gateshead; in the other towns they caused the lowest death-rates in Derby, Preston, and Huddersfield, and the highest rates in Wolverhampton, Liverpool, Salford, and Burnley. The greatest mortality from measles occurred in Manchester, Salford, Liverpool, Bolton, and Burnley; from scarlet fever in Halifax; from whooping-cough in Salford, Oldham, Burnley, Plymouth, and Bristol; and from "fever" in Croydon. The 42 from deaths from diphtheria included 33 in London, 3 in Liverpool, and 2 in Cardiff. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three towns. There were 13 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 22nd inst., against 12, 11, and 14 at the end of the three preceding weeks; one new case was admitted during the week, against 6, 3, and 6 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2508, against 2380, 2385, and 2416 on the three preceding Saturdays; 311 new cases were admitted during the week, against 223, 231, and 239 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 232 and 198 in the two preceding weeks, rose again last week to 220, but were 98 below the corrected average. The causes of 39, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Nottingham, Hull, and in thirteen other smaller towns; the largest proportions of uncertified deaths were registered in Salford, Preston, Sheffield, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·7 and 20·8 per 1000 in the two preceding weeks, further rose to 22·3 during the week ending May 22nd, and was 5·1 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·4 in Greenock and 18·8 in Aberdeen to 25·2 in Paisley and 26·9 in Edinburgh. The 664 deaths in these towns included 49 which were referred to measles, 35 to

Hosted by Google

whooping-cough, 14 to diarrhœa, 5 to diphtheria, 4 to scarlet fever, and 3 to "fever." In all, 110 deaths resulted from these principal zymotic diseases, against 93 and 102 in the two preceding weeks. These 110 deaths were equal to an annual rate of 3·7 per 1000, which exceeded by 2·0 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 29 and 41 in the two preceding weeks, further rose to 49 last week, and included 30 in Edinburgh, 15 in Glasgow, and 4 in Leith. The deaths referred to whooping-cough, which had declined in the three preceding weeks from 45 to 29, rose again to 35 last week, of which 16 occurred in Glasgow and 9 in Edinburgh. The 4 fatal cases of scarlet fever showed a decline of 2 from the number in the preceding week, and included 3 in Glasgow. The deaths from diphtheria, which had been 6 and 5 in the two preceding weeks, were again 5 last week, of which 2 occurred in Glasgow and 2 in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 134 and 108 in the two preceding weeks, rose again to 135 last week, and were 43 above the number in the corresponding period of last year. The causes of 39, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 33·7 and 28·3 per 1000 in the two preceding weeks, further declined to 27·3 during the week ending May 22nd. During the past seven weeks of the current quarter the death-rate in the city has averaged 31·1 per 1000, the rate during the same period being 16·4 in London and 26·5 in Edinburgh. The 183 deaths registered in Dublin during the week under notice showed a decline of 7 from the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against numbers declining from 41 to 19 in the four preceding weeks; of these, 6 resulted from whooping-cough, 5 from measles, 2 from diphtheria, 2 from "fever," but not one either from small-pox, measles, or diarrhœa. These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rate during the same period being 1·3 in London and 7·8 in Edinburgh. The fatal cases of whooping-cough, which had been 16 and 6 in the two preceding weeks, were again 6 last week. The deaths from measles, which had declined in the four preceding weeks from 19 to 6, further fell to 5 last week. The 2 deaths referred to "fever" corresponded with the number recorded in the preceding week, while the mortality from diphtheria showed an increase. The 183 deaths in Dublin last week included 38 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths of infants exceeded those recorded in the preceding week, while those of elderly persons showed a decline. Three inquest cases and 4 deaths from violence were registered; and 59, or nearly a third, of the deaths occurred in public institutions. The causes of 9, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN HERBERT L. G. CHEVERS retires from the Service, receiving a gratuity. Brigade-Surgeon-Lieutenant-Colonel M. M. Gallwey has been appointed Recruiting and Embarking Medical Officer, Southern District at Portsmouth. Surgeon-Captain E. Corcoran has embarked for Sierra Leone, and Surgeon-Captain R. Holyoake for South Africa.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain G. S. Thomson (Bombay) are placed temporarily at the disposal of the Government of Bombay for employment on plague duty. The services of Surgeon-Captain W. E. Hardy, A.M.S., are placed temporarily at the disposal of the Foreign Department for plague duty. Surgeon-Major Bull to be Staff-Surgeon, Poona, vice Surgeon-Lieutenant-Colonel Young, retired. 4th Bombay Rifles: Surgeon-Captain Bennett to the Medical Charge, vice Surgeon-Major Bull, transferred. Surgeon-Captain W. H. B. Robinson (Bengal), Medical Officer of the 34th Bengal Infantry, is appointed to officiate as Civil Surgeon of Bikanir, vice Surgeon-Major W. H. Neilson, and until further orders.

NAVAL MEDICAL SERVICE.

The following appointments are announced: — Fleet-Surgeons: Edward E. Mahon, C.B., to the *Excellent;* Herbert M. Ellis to the R.M. Artillery, Eastney; Michael Fitzgerald to the *Majestic;* and Anthony Gorham, M.D., to the *President*. Staff-Surgeons: Alexander J. J. Johnston to the *Victorious*, and John Acheson, M.D., to the *President*, additional, for R.N. Rendezvous.

YEOMANRY CAVALRY.

Lanarkshire: Surgeon-Captain R. E. Wood to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 1st Worcestershire and Warwickshire: Surgeon-Captain D. Rice resigns his commission. *Rifle:* 1st Volunteer Battalion the Buffs (East Kent Regiment); Surgeon-Lieutenant A. Murdoch resigns his commission.

Consequent upon the division of the 2nd Volunteer Battalion the Royal Welsh Fusiliers into two Battalions, designated respectively the 2nd Volunteer Battalion the Royal Welsh Fusiliers and the 3rd Volunteer Battalion the Royal Welsh Fusiliers, Her Majesty has been graciously pleased to approve of the following transfers of officers from the 2nd Volunteer Battalion to the 3rd, and are considered to have received in the new Battalion commissions of the same rank and date as those previously held by them in the 2nd Volunteer Battalions, viz.:—R. A. Prichard, Surgeon-Captain; W. J. Morris, Surgeon-Captain; T. E. Jones, Surgeon-Captain; T. L. K. Davies, Surgeon-Captain; and E. T. Hughes, Surgeon-Lieutenant.

THE ROYAL MILITARY TOURNAMENT.

The Royal Military Tournament, which was opened by the Prince of Wales on Thursday, May 27th, must be this, the eighteenth year, looked upon as an unqualified success from almost every point of view. As a spectacular entertainment the organisers of the Tournament are certainly to be congratulated, and the audience have no cause to grumble at the quantity and quality of spectacle provided. The pageant, "Our Army, 1704—1882," is representative of the growth and progress of the British standing army from early times up to the present day, and is commemorative of the four renowned victories of Blenheim, Waterloo, Inkerman, and Tel-el-Kebir. The display by the New South Wales Rifles will no doubt prove popular with the public, as will also the military cycling display by members of the 26th Middlesex (Cyclist) R.V. The latter display is distinctly good, but we think that it shows the use of the cycle in warfare as seen at the Agricultural Hall rather than on the actual battle-field. "Throwing the djerid" by the Zaptiehs, or Cyprus Military Police, and the war dance by the Aboriginal inhabitants of Borneo, the Dyaks, are interesting performances, but might, we think, be curtailed with advantage. The musical drive by the Royal Horse Artillery and the naval display form not the least noteworthy items on the programme, and the musical double ride—which will be given during the first week of the Tournament by the 3rd (Prince of Wales's) Dragoon Guards—continues to receive the applause which it so rightly deserves. The display by the Army Gymnastic Staff, of which we hope to say a word later, does great credit to those who have had charge of their training. The usual competitions will take place of course from day to day, and the combined display of all arms closes each performance. A most desirable improvement in this display is the comparative absence of the deafening noise of the machine guns and also of the smell of burnt powder which characterised previous performances.

The principal medical officer in charge of the Tournament is Surgeon-Major A. C. A. Alexander (Coldstream Guards), who is assisted by Surgeon-Major J. E. R. James, A.M.S.

THE GORDON BOYS' HOME.

The late General Charles Gordon may be said to have been the central figure of chivalry, purity of motive, and unselfish devotion to duty of his age. His death at Khartoum, on Jan. 26th, 1885, caused a feeling of deep regret in this and other countries, and it was a good idea to start as a memorial to him a home for the training and education of necessitous lads to fit them for service in the army and navy or for earning a livelihood in trade. Since the institution was started

Hosted by Google

865 boys have passed through it, 344 of whom have joined the army, navy, and colonial forces, and 241 have been provided with civil employment. These boys have almost universally turned out well, according to the characters that have been received of them. The education at the home is of a most practical character and well fitted to make them useful, law-abiding citizens. Officers of the public medical services will be glad to have learned recently from the Duke of York that in this Jubilee year of Her Majesty's sixty years' reign the Home is making progress. It is an institution that well deserves support, and it fulfils a very useful purpose and one that Gordon had most sincerely at heart.

THE BENIN DESPATCHES.

Despatches from Admiral Rawson, Consul-General Moor, and others were published in the *London Gazette* of the 7th inst. Among the officers mentioned and specially commended by Admiral Rawson are the following: Fleet-Surgeon M. Fitzgerald, for having organised the medical department and rendered every assistance. Staff-Surgeons E. R. Dimsey, of the *Phœbe*, and J. McC. Martin, of the *Forte*, were with the flying column, and upon them fell the whole work of attending the wounded and bringing them down. Surgeon R. T. A. Levinge, of the *Alecto*, is specially mentioned in Captain MacGill's despatch. Surgeon C. S. Facey, of the *Widgeon*, is mentioned in Captain O'Callaghan's despatch. Surgeon F. H. A. Clayton, of the *St. George*, although ill himself, worked most assiduously with the sick. Dr. R. D'Arcy Irvine, of the Niger Coast Protectorate, volunteered for, and was attached to, the Sapoba force; he was also most assiduous in his attention to the sick at Warrigi when there was no naval medical officer present.

MOBILISATION OF NO. 5 FIELD HOSPITAL.

The *Irish Times* of the 21st inst. gives an account of the recent mobilisation of this field hospital at Island Bridge Barracks on the 19th inst. under the command of Surgeon-Lieutenant-Colonel Greene. Major-General Viscount Frankfort, in the absence of Lord Roberts, accompanied by several staff officers and Surgeon-Major-General Preston, Principal Medical Officer of Ireland, inspected the hospital, and expressed his warm approval of the highly satisfactory manner in which every detail was carried out. A hospital was prepared for the accommodation of 100 sick, with all necessary arrangements, in a very short space of time. The *personnel* of a field hospital consists of four medical officers, one quarter-master, one warrant officer, and thirty-nine non-commissioned officers and men. Provision is made for 100 sick, the Army Service Corps finding the waggons, &c., necessary for transport.

THE BENIN EXPEDITION AWARDS.

The Queen has given directions for the following appointment to the Most Distinguished Order of Saint Michael and Saint George in recognition of services rendered in connexion with the recent expedition to Benin:—To be Ordinary Member of the Third Class or Companion of the Most Distinguished Order: Fleet-Surgeon Michael Fitzgerald, Royal Navy. Her Majesty has also given orders for the following appointments to the Distinguished Service Order in recognition of the services of the undermentioned officers during the same expedition:—To be Companions of the Distinguished Service Order: Staff-Surgeon James McCardie Martin, Royal Navy; and Staff-Surgeon Edgar Ralph Dimsey, Royal Navy.

THE LATE GRECO-TURKISH WAR.

According to the accounts which have appeared as to the medical arrangements of the Greek Army these do not appear to have been at all satisfactory. There seems to have been an absence of organisation, and the sufferings of the sick and wounded, owing to the want of proper care, are stated to have been considerable. Owing to the heavy rainfall to which the army was exposed at Domoko there was a large amount of sickness and the hospitals are crowded.

BELGAUM.

We learn by the last mail from India that cholera has been very prevalent of late in the villages to the south-east and south-west of Belgaum, and that several cases have occurred in that city and the Sudder bazaar. There were also two fatal cases in the East Yorkshire Regiment at that station.

Two new companies (Berkshire and Kent) have been added to the Militia Medical Staff Corps. For commissions in these companies immediate application should be made to the officer commanding Militia Medical Staff Corps, Aldershot.

THE CALOMEL BATH.

To the Editors of THE LANCET.

SIRS,—The first experiments with regard to the action of the calomel bath were made in a small room, the air of which necessarily became impregnated with the vapour. The result was that the action on the gums was quickly produced, and ten grains of calomel was generally sufficient to produce the required effect. In an ordinary room a drachm may be used to begin with. It is well that the calomel should be pure and not contain any free hydrochloric acid, which if breathed is apt to irritate the lungs. The presence of acid is readily ascertained by holding a piece of moistened litmus paper over the fumes. Messrs. Allen and Hanbury informed me that they kept the pure calomel. Mr. Lowe of Stafford-street was in the habit of having the calomel resublimed in order to get rid of any free acid which ordinary calomel generally contains. Mr. Lowe has also a box for administration of the calomel bath; with this apparatus very little of the calomel is breathed. The principal advantages of the administration of mercury by the calomel bath over some other modes of giving it are (1) it is clean and requires little exertion on the part of the patient, and (2) it does not irritate the digestive organs; but (3) by far the most important point is that it determines any action that may be taking place to the skin, and thereby prevents the affection of the internal organs. I can scarcely recall a case in which the treatment was commenced by the calomel bath and properly carried out in which the deeper structures were affected. In one case a patient, who had previously undergone a variety of treatment and had a hole in his hard palate before he commenced the treatment, did not recover. In this case nearly the whole of the outer table of the frontal bone perished. The calomel bath has no influence upon the local or suppurating sore. With cleanliness this will heal without any specific treatment.

In the House of Lords recently Lord Lister mentioned that there was one matter which he did not like in the Act of 1866—viz., that when a woman was pronounced to be clear of disease she received a certificate which she was to carry about with her. This could be no real protection to others. It is true that after a patient has been affected with constitutional syphilis he is much less likely to take the disease again; but this does not apply to the local form of the disease—a patient supposed to be cured one day may be re-infected the next.

I am, Sirs, your obedient servant,

HENRY LEE.

Queensborough-terrace, Hyde-park, W., May 19th, 1897.

"THE QUESTION OF THE SECOND OVARY IN OVARIOTOMY."

To the Editors of THE LANCET.

SIRS,—The diverse opinions expressed by the various writers on this question show how important it is to discuss temperately and without personal bias methods of procedure that may require re-consideration if performed under new conditions and in the light of greater experience. Aseptic surgery has so revolutionised all surgery that every operation requires to be re-considered in the light of the greater safety conferred upon it by antiseptic precautions, and no statistics are of the slightest value collected before this era, or, indeed, in the earlier imperfect stages of this period.

The question which I raised was whether the age of the patient might not be regarded as a determining factor where it was necessary to remove one ovary, and the other was found in an early stage of simple cystic degeneration, not yet robbed of its function, or likely soon to cause inconvenience. The plea was put forward for a girl or young woman who might thus still be allowed the chance of becoming a mother, a natural instinct which in many women—and I would say in the best women—is stronger than the love of life itself. That this suggestion is contrary to the practice hitherto generally

Hosted by Google

adopted renders it worthy of discussion in your columns. Its justification rests on the greater safety of all abdominal operations under modern conditions, so that a second operation need not be regarded as very formidable, if eventually necessary.

The case I gave in illustration was that of a young woman of exceptionally attractive appearance, whose diseased ovary having a long pedicle and not a single adhesion was removed without any exposure of the abdominal contents. The other, with a cyst on its anterior surface, I thought too good to remove. The abdomen was closed, and she was convalescent without any complication in a fortnight. So far as the technique of the operation was concerned it might have been performed by any assistant surgeon's dresser with a knowledge of ligatures and sutures. I have to thank Dr. Duncan for his suggestion of excising the cyst and leaving the ovary. On one occasion when I attempted this it resulted in so much damage that I excised the ovary, and my object was to leave an ovary not robbed of the function of reproduction. On questioning others of large experience I find they have met with similar difficulties in attempting to enucleate ovarian cysts. It will be seen that Mr. Doran and Dr. Duncan are in direct opposition, for whereas the former relates how in a woman aged fifty years he left a suspicious second ovary which eventually required a second operation Dr. Duncan says: "I go further, and say that in *all* cases of ovariotomy near or after the menopause the second ovary should invariably be removed, whether it looks healthy, cystic, or atrophied." The ovaries at this period being functionally either inactive or approaching inactivity, any suspicious ovary should, in my opinion, certainly be removed, but we perhaps want further experience before adopting, as a rule, Dr. Duncan's suggestion in the case of a healthy ovary, since the parallel double operation in men is sometimes followed by nervous symptoms that it is possible a single organ, though atrophied, may prevent. Dr. Thomson's communication in THE LANCET of May 8th is of great interest and importance, showing how long cases of cystic tumour of the ovary may remain quiescent without causing much inconvenience. His case, in which the patient had had two children during the four years he had recognised the existence of an ovarian tumour, has a special bearing on my argument. It would not be difficult, I think, to collect a good many cases where a cyst has been known not to increase for years or where the tumour has actually decreased or disappeared. May not the one ovary be allowed this possibility in a young person where its functional relation to the Fallopian tube remains intact?

Exception has been taken to my description of a young woman deprived of her ovaries as "an unnatural monster, cut off from the next generation." This has arisen from the confusion of two distinct ideas included in the same term—a potent cause of logical fallacy—viz., the child's bogey, meaning a huge repulsive beast—and the same term, as generally applied in medicine, meaning simply an abnormality, not necessarily in any way repulsive, large, or even obvious. The siren, with her tail immersed, is represented as a seductively beautiful woman, but her aquatic tail being abnormal to the human ideal renders her a monster. The second proposition, that if not previously a mother she is "cut off from the next generation" is so obviously correct as not to require further comment. The medico-legal question included in the sentence, "if married with this condition secreted [viz., loss of both ovaries] would, I presume, be liable to be divorced," has also been adversely commented upon, but I have taken a very good legal opinion on the subject, and am assured that as marriage is a legal contract, in which the procreation of children up to a certain age is definitely stated as one of the objects, fraudulently to conceal an absolute and artificial bar to this part of the contract would be a good ground for divorce.

I am, Sirs, yours faithfully,

R. CLEMENT LUCAS, B.S. Lond., F.R.C.S. Eng.,
Surgeon to Guy's Hospital.

Wimpole-street, W., May 15th, 1897.

THE LIABILITY TO CANCER IN OLD AGE.

To the Editors of THE LANCET.

SIRS,—A point of general interest was raised in a recent discussion at a meeting of the Life Assurance Medical Officers' Association, but time did not admit of its being followed out in detail. The age-incidence of cancer as a cause of death was well shown by a table derived from the Registrar-General's returns. During childhood and early life the mortality from cancer per million living is, of course, very small; it increases in middle life, especially in women, and becomes considerable in the decade forty-five to fifty-five, and large in subsequent decades, increasing slightly to the end of life. Now there is an impression derived from clinical experience that whilst malignant disease is common in the earlier period of old age, yet when a person safely reaches sixty-eight or seventy years (as the President put it at the meeting above) he is less likely to die from cancer. The above statistics seem to confute this. But the clinical impression has a basis of fact. For the mortality from cancer must be looked at also, as shown by Dr. J. F. Payne, whose lucid paper opened the discussion, in its relation to other causes of death. Comparing it in this way—I take the figures from the Supplement to the Registrar-General's Fifty-fifth Annual Report, giving the mortality in England and Wales for the ten years 1881-90—the deaths from cancer, which are as 1 to 59 of all deaths between the ages of twenty-five and thirty-five, increase to 1 to 20 in the decade thirty-five to forty-five, 1 to 11 between forty-five and fifty-five, and the same between fifty-five and sixty-five, but after this they decline to 1 to 16 from sixty-five to seventy-five, and are only 1 to 36 after seventy-five years of age. For females alone the proportion is throughout higher, and at the ages of prevalence is: from thirty-five to forty-five, 1 to 12; from forty-five to fifty-five, 1 to 7; from fifty-five to sixty-five, 1 to 8; and from sixty-five to seventy-five, 1 to 13.

Relatively, then, to other causes of death cancer attains its maximum soon after the middle period of life, between the ages of forty-five and sixty-five years; and although in later old age the actual liability does not diminish, but even increases a little, the relative liability, as compared with other diseases, diminishes greatly. Hence, although it is not strictly accurate to say that a man who escapes cancer up to seventy years of age is less likely to be attacked, there is this ground for the current belief, that he is much more likely to die from something else. Cancer is accountable for a much smaller proportion of deaths at these later ages.

The Registrar-General's report for the decade 1881-90 deals also with the local distribution of cancer; the mortality at ages over thirty-five years, in proportion to the population living at such ages, is taken to avoid inequalities arising from differing age conditions. London, as is well known, takes the lead with a mortality of 2250 per million; of course, the special hospitals are partly responsible for this. The higher rates are mostly found amongst the eastern and south-eastern counties, especially Huntingdonshire, Cambridgeshire, and Sussex; whilst in the southern, western, and midland counties the cancer death-rate is apt to be low. Dorset, Bucks, and Monmouth enjoy the least mortality at about 1578 per million; the rate for all England and Wales is 1844.

I am, Sirs, yours truly,

Finsbury-square, May 11th, 1897. R. HINGSTON FOX.

FOREIGN MEDICAL STUDENTS AND PRACTITIONERS IN FRANCE.

To the Editors of THE LANCET.

SIRS,—The campaign which has so long been waged against the invasion of French medical schools and practice by foreigners has made considerable progress during the past twelvemonth. During this period no legislation bearing upon the subject has been enacted, but Ministerial decrees and circulars have been issued materially modifying the regulations heretofore affecting foreigners. For those not intending to practise in France a degree of Doctor of Medicine has been created which, like that conferred by the German universities, does not entitle the holder to practise in the country where it is obtained. Aspirants to this degree may matriculate (upon approval of certificate showing the completion of studies approximately equivalent to those of the French *lycées*) and take the regular course at any French medical school except that of Paris. In these cases the candidate possessing a foreign medical degree is exempted from a portion of the course and examinations, the extent of such exemption varying with the value of the foreign diploma as determined by the French faculties. Whereas the creation of the new degree of an honorary character now enables the foreigner

Hosted by Google

to obtain a French medical diploma somewhat more readily than of late years, the privilege of practising within the territory of the French Republic is more difficult to acquire than before. To obtain this the foreigner, whether merely a student or the possessor of a foreign medical diploma, must not only pass all of the examinations of the regular medical course, but must now matriculate upon precisely the same condition as the native student. He may do this either at the Paris or at a provincial medical school. However, the requirements for matriculation are now such that a much more intimate knowledge of the French language is necessary for these than for the more or less technical oral examinations of the regular medical course. For this reason the present conditions are practically prohibitive unless the foreigner has been educated in France or is prepared to spend a number of years in preparation. The present requirements for foreigners and natives alike are as follows.

For Matriculation.—1. The degree of Bachelier de l'Enseignement Secondaire Classique (Lettres-Philosophie). 2. A certificate from a Faculté des Sciences of satisfactory examination in Chemistry, Physics, Zoology, and Botany after a year's study in the said Faculté.

For the Medical Course.—1. Examination: (*a*) Anatomy, and (*b*) Dissection. 2. Examination: Histology, Physiology, Biological Physics, and Chemistry. 3. Examination: Part 1: (*a*) Operations (on the cadaver) and Topographical Anatomy; and (*b*) Surgery (theory), Obstetrics (theory). Part 2: (*a*) General Pathology, Animal and Vegetable Parasites, and Bacteriology; and (*b*) Practice of Medicine (theory) and Pathological Anatomy (necropsy). 4. Examination: Therapeutics, Hygiene, Forensic Medicine, Materia Medica, and Pharmacology. 5. Examination, Part 1: (*a*) Surgery (clinical) and (*b*) Obstetrical (clinical). Part 2: Medicine (clinical). 6. Thesis upon subject of student's choice.

Whereas the increased requirements demanded of aliens have given rise to adverse criticism by a portion of the foreign press, there is, in reality, no discrimination made in favour of the native. It should be remembered that the foreigner is *ipso facto* exempt from the military service required of every able-bodied Frenchman. The usual three years of obligatory service are reduced to one for students of the liberal professions, but these must lose that year when in the midst of their work. On the other hand, the foreign student in France pursues his course without interruption and prepares in all serenity for the competitive examinations admitting to the coveted post of interne in the hospitals, while his French comrade is struggling to regain the ground lost during a twelvemonth "in the ranks."

In conclusion, the present situation may be summed up as follows, viz.:—1. The foreign medical student or practitioner unable to matriculate upon the same conditions as the native student must pursue his studies at a provincial school, and although he may obtain the French doctorate degree it will not admit him to practise upon the territory of the French Republic 2. The foreign medical student or practitioner may qualify for practice in France and her colonies by matriculation and completion of the full course at any French medical faculté upon precisely the same conditions as the native student.

I am, Sirs, yours faithfully,

FREDERICK O. CHAMBERLAIN, M.D.

Avenue de l'Opéra, Paris, May 17th, 1897.

"EXCISION OF PAROVARIAN CYSTS WITHOUT REMOVAL OF THE OVARY OR TUBE."

To the Editors of THE LANCET.

SIRS,—The communication by Dr. Howard Kelly referred to by you in THE LANCET of May 22nd on page 1427 shows very clearly how difficult it is to get new facts accepted, or how readily the profession forgets established facts, and brings them up again as novelties. Still, we don't expect such proceedings from such places as the Johns Hopkins University. In 1874[1] I wrote, "The Fallopian tube was normal and had no other relation to the tumours than slight connexion by loose areolar tissue (as had also the ovary). . . . In an ovariotomy I had performed not long before I was struck by the fact that the ovary was perfectly healthy and separated from the tumour, as was also the tube, by a mesovarium of some extent; in fact, I did not do ovariotomy at all in the removal of the tumour, for in passing the chain of the ecraseur round its base I did not include either the tube or the ovary, and they were both returned into the abdominal cavity. The consideration of these facts led me to examine some tumours I had removed previously, and others removed by friends, and I have since subjected specimens to careful examination for confirmation of my accidental observation. The result has been that in every truly unilocular tumour I have found the ovary unaffected, though on several occasions I have found it stretched over the cyst wall."[2] In my fourth edition (1883) I developed these views further, and added: "In the records of ovariotomies performed these cases have, up till now, always been stated as ovariotomies, and the ovaries and tubes associated with the tumour have been removed with it. Both the record and the removal of the ovary are mistakes. The operation is not an ovariotomy at all, and nine times out of ten both ovary and tube might easily be separated from the tumour and left, and this practice I now always try to follow. It is very curious that those who are crying out most loudly against the unnecessary removal of ovaries have been in the habit of pursuing this practice in the case of parovarian tumours without compunction."

In my more recent work[3] I give a great deal more precise, and some very curious, information concerning broad ligament cysts. I have yet to publish the details of my more recent methods of operating in these and other cases, but I may here say that I have not removed an ovary or tube in one of them for at least twelve years. In the early part of April of the present year I had a run of three of these and had in each case to enucleate the whole tumour from its broad ligament bed in order to leave the healthy ovary and tube. Therefore it was that I condemned the proceedings of Mr. Clement Lucas as reported by himself in THE LANCET.

The conclusion from an immense experience going over thirty years is that such a thing as a unilocular tumour of the ovary does not exist save in one bottle which I placed in the museum of the Royal College of Surgeons as an example of an exception which proves the rule.

I am, Sirs, yours faithfully,

Birmingham, May 22nd, 1897. LAWSON TAIT.

ON CERTAIN AFFECTIONS OF THE NERVOUS SYSTEM IN CYCLISTS.

To the Editors of THE LANCET.

SIRS,—I have been much interested in the facts recorded in a recent paper published in THE LANCET by Dr. James Taylor and Dr. Semple,[4] and I should like to record certain facts that have come to my notice in reference to the nervous symptoms exhibited by some people after cycle riding. My experience was practical rather than medical, for it was gained chiefly during the years 1885 and 1886, when I was an amateur champion cyclist, and knew most of the path- and road-racing cyclists in London, but when I had had no medical training to enable me to observe neurological phenomena. In the long-distance road races it was common to lose sensation in the feet, and several accidents occurred through slipping a pedal from this cause. This was one of the reasons why toe-clips were so universally used. When the men dismounted their gait was unsteady, the legs jerked out straight, and the feet stamped on the ground. I have noticed these things many times, not only in others, but in myself. Numbness in the perineum and penis and difficulty in beginning the act of micturition were quite common symptoms. I can remember the finish of one long-distance road race, when one of the competitors had involuntarily passed both urine and fæces during the race without being aware of the fact. I cannot call to mind any case in which the symptoms mentioned above did not pass off after a period of more or less prolonged rest. That severe exertion is not necessary to produce nervous symptoms is well exemplified in my own father's case. He learned to ride a bicycle when he was about sixty-two years old. A comparatively short ride produced numbness, trembling, and loss

[4] THE LANCET, April 17th, 1897.

Hosted by Google

of muscular sensation in his arms and legs. This was so marked that the power of writing was lost for the rest of the day after a ride of a few hours. He persevered for a while, but ultimately had to give up cycling altogether. The question how these symptoms are produced is one of much interest. Three factors are evidently of the greatest importance—viz. (1) pressure; (2) vibration; (3) auto-intoxication with waste products due to overwork.

1. *Pressure.*—The pressure of a bad saddle will undoubtedly produce nervous symptoms in the perineal region; any cyclist can verify this fact for himself without much difficulty. A really perfect saddle has yet to be invented, and when it is it will be impossible to press injuriously on the perineum, whatever position the rider assumes. Leaning forward on a cycle lessens the surface of the body exposed to the wind and decreases the effort necessary to propel the machine against a head wind. For this reason it is impossible to prevent large numbers of riders from adopting this attitude. Of late years the position of the saddle in relation to the pedals has been altered. In the modern cycle the saddle is placed much further forward than it used to be. The result of this is that with the ordinary form of saddle the position which is necessarily assumed leads to the weight being wholly borne by the perineal structures.

2. *Vibration.*—That this is of some importance will be readily granted by anyone who has ridden both solid and pneumatic tyred machines. Though pneumatic tyres have done away, to a very large extent, with vibration, the jolting on a rough road giving a succession of shocks to the body must be taken into account. The difference in comfort to the feet between rubber and rat-trap pedals is also well known. Numbness in the soles of the feet would be less likely to occur with rubber than with metal pedals. That vibration alone would produce these symptoms is not probable, for none of the twenty-three railway engine-drivers and firemen whom I have questioned on this point have ever noticed any numbness or loss of power after a day's work.

3. *Auto-intoxication with waste products due to overwork.*—During severe or prolonged exercise the untrained man rapidly dissipates his reserve tissues, and his excretory organs being unable to eliminate the waste products of metabolism he suffers from an auto-intoxication, shown either by a febrile condition, sometimes of great severity, or general nervous prostration or excitability, which often prevents appetite or sleep. It is probable that all these three factors, and possibly others, are concerned in the production of the nervous symptoms that have been observed.

I am, Sirs, yours faithfully,

PERCY FURNIVALL, F.R.C.S. Eng.,
Assistant Demonstrator of Anatomy, St. Bartholomew's Hospital; Assistant Surgeon to the Metropolitan Hospital.

May 24th, 1897.

FORCED REDUCTION OF THE DEFORMITY IN CARIES OF THE SPINE.

To the Editors of THE LANCET.

SIRS,—In your short report of a meeting of the British Orthopædic Society which appeared in THE LANCET of May 15th, it is stated that in speaking of Dr. Calot's treatment of Pott's disease, I "questioned if it were possible that such a procedure had been followed by the results described." As this statement by itself must give a different impression from that which would appear from my full remarks I beg you to allow me to add to it. It is now probably well known to your readers that Dr. Calot of Berck-sur-Mer reduces the deformity in caries of the spine by forcing the parts into a straight position under chloroform and then applies a fixation apparatus in which he keeps his patients from five to six months. At the end of this time he states that the patients are absolutely cured. It was the possibility of cure in this short time which I questioned.

The practice of straightening the spine in Pott's disease is, of course, not new, and it has been objected to by various surgical authorities. Samuel Hare, however, who published a work in 1838[1] and who was looked upon as a most reliable and skilful surgeon, having great experience with this disease, was a strong advocate for reduction of deformity, and in his work (p. 91) he gives two illustrations showing the position of the carious bones (1) in their angular position, and (2) when straightened out. I think there is much to be said in support of this method, and although I have never attempted, like Dr. Calot, to separate the diseased parts by any great force I have aimed at improving the whole position of the back, chiefly by altering the curve above and below the seat of the disease. By this means in a great many cases the abnormal projection has become markedly less, as shown in many of the illustrations in my book, "Caries of the Spine." (I would especially refer to Figs. 80–81 and 87–88 in that publication.) Sometimes the projection has completely disappeared, and when this has occurred one cannot but suppose that the diseased bones have been separated at the seat of caries, and I have only seen good results from firm but gentle pressure upon the gibbosity by means of a fixation apparatus. The objection which has generally been raised against attempting to straighten out the spine has been founded upon the view that if the bones were separated the space would be so great that there would be little chance of re-formation of bone. This view I proved to be incorrect at a demonstration given at the annual meeting of the British Medical Association at Bournemouth in 1891.[2] A description of the case and specimen referred to are also given on pages 121 to 124 in "Caries of the Spine." The specimen and the history of the case show the following facts: (1) that a very large gap may occur from dissolution of several vertebræ without their usual spontaneous coalescence, the spinal cord being left exposed in the thorax and abdomen, unprotected by a bony covering; (2) that repair may take place while the undestroyed vertebræ remain separated from one another;[3] (3) that repair of this kind can progress in spite of the most adverse circumstances in respect to the general health of the patient; and (4) that in such a severe case the new bony growth requires a much longer time to become thoroughly solid than in ordinary cases.

As regards the period of repair, in the case I allude to the patient so far recovered that on Sept. 3rd, 1882, eight months after I had first seen him, he was able to walk about comfortably and his health had improved very greatly. He continued to improve apparently in every way until September, 1884, when he died from tubercular meningitis—that is to say, two years and eight months from the time I had first seen him—and it may be assumed that repair had been in active progress during at least the latter two years. Upon examination after death it was found that the gap had been filled up by bony growth, but when the affected vertebræ were being macerated all this new bone crumbled away, leaving the vertebræ as they were before the repair had taken place; therefore this case shows that two years were not sufficient to thoroughly consolidate the new bone, and, although in some patients the progress of repair may be more rapid, yet I cannot imagine that six months, as stated by Dr. Calot, would be anything like sufficient to effect a cure in any case where a considerable gap had to be filled up.

As to danger from immediate and forced reduction it may be assumed that all the cases operated upon by Dr. Calot have been in a state of active disease before repair has commenced, but should new bone have been already thrown out there would be considerable danger of producing irritation by the loosened particles of bone from the new growth, which would act as foreign bodies. A case came under my notice some few years ago which bears evidence to this effect (Case 102, page 135 in "Caries of the Spine"). It seems probable that immediate reduction may prove to be a valuable method of treatment in suitable cases, and I congratulate Dr. Calot upon his success. I question, however, if it be possible to cure such cases in six months.

I am, Sirs, yours faithfully,

Queen Anne-street, W., May 24th, 1897. NOBLE SMITH.

[1] Practical Observations on the Prevention, Causes, and Treatment of Curvatures of the Spine. London, 1838.

[2] Brit. Med. Jour., March 19th, 1892.

[3] Mr. Jackson Clarke remarks upon this fact that when the anterior common ligament remains intact at the seat of disease the periosteum will probably be attached to it and is then capable of forming new bone.

"RIGHT-HANDEDNESS."

To the Editors of THE LANCET.

SIRS,—In discussing the question whether the "faculty of bipedal progression in an erect posture" is an acquisition it is necessary to clearly define what we mean by this latter term. May I be allowed in this connexion to quote from my work, "The Causation of Disease"? "Scientifically it is

Hosted by Google

perfectly justifiable to distinguish sharply between the hereditary and the acquired; practically, however, it is quite impossible. Scientifically we may distinguish as follows. If an individual is exposed to as negative an environment as is compatible with life it is evident that there will be little or no acquisition. We may, for purposes of argument, assume such a negative environment, one, namely, under which an individual will pass through a series of developmental changes, which are the outcome of heredity pure and simple—i.e., altogether independent of external influences. It is, of course, impossible really to exclude altogether the influence of environment, since life is due to the inter-action of the organism and its environment ..... but we are justified in theoretically supposing an individual to pass through life under such a limited environment as that referred to, and we may speak of the individual such as he would then be as the strict and sole product of heredity. What he is capable of becoming under particular environments belongs to the region of acquisition" (pp. 140-1). Accepting this definition, it will be seen that the faculty of bipedal progression in an erect posture can scarcely be regarded as an acquisition. Certainly the view held by Dr. Reid, that the infant learns to walk by imitation, is erroneous—so erroneous, indeed, as to shake one's faith in Dr. Reid's other generalisations. No doubt the functional activity of the locomotor apparatus is needful for its full development and for the full development of the faculty of walking in man, but I imagine the majority of physiologists will agree with Dr. Bastian in regarding this faculty as essentially hereditary. Respecting Dr. Reid's lengthy argument in favour of language being a pure acquisition, I cannot think he can have properly interpreted Dr. Bastian's views on the subject.

I am, Sirs, yours faithfully,

Wimpole-street, May 17th, 1897. HARRY CAMPBELL.

"FRACTURES OF LONG BONES IN SCURVY-RICKETS."

To the Editors of THE LANCET.

SIRS,—The case brought by Dr. Guthrie before the Medical Society of London under the above title was one of extreme interest from a diagnostic point of view. He believed that the fractures were due to scurvy, and Mr. Morgan pointed out that in scurvy-rickets fractures of the long bones are usually near the epiphysis and not in the centre of the shaft. This term "scurvy-rickets" is confusing because of its loose application, and for clinical purposes it might be more precise to use the terms (1) scurvy, (2) rickets, and (3) scurvy associated with rickets. I think that this distinction has been definitely proved by Dr. Cheadle, Dr. Barlow, and others. My own experience has been that in scurvy in infants hæmorrhage may occur under any part of the periosteum, and when the shaft is completely separated from the periosteum by blood, complete transverse or oblique fracture may be caused merely by handling the limb. Such fractures may be at the epiphyses or in the centre of the shaft. In rickets the process is one of softening and bending of the long bones, with possibly greenstick fracture of the shaft. In scurvy associated with rickets the hæmorrhage is usually near the epiphysis, which becomes separated, as Mr. Morgan pointed out; and even if the effusion of blood extends along the shaft the bone does not appear to have the same brittleness as in uncomplicated scurvy, and fracture in the centre of the shaft is not common. I agree with Dr. Guthrie in his diagnosis of scurvy, and I should suggest that when these fractures occurred there was probably an absence of marked rachitic changes in the bones. As regards the other point he raises—whether the fracture leads to the hæmorrhage or the hæmorrhage to the fracture—I think the latter view is probably correct. One frequently meets with subperiosteal hæmorrhage without any fracture of the bone, but I have never heard of a case of fracture of a bone in scurvy which was not accompanied by subperiosteal hæmorrhage.

I am, Sirs, yours truly,

May 11th, 1897. G. A. SUTHERLAND.

"A QUESTION OF COURTESY."

To the Editors of THE LANCET.

SIRS,—I am not in the habit of seeing your valuable paper, nor did I ever imagine that I should be called on to ask you to publish a letter from me; but since a copy of your issue of May 8th has been shown to me, and my attention has been drawn to a letter headed "A Question of Courtesy," which deals with a case in my parish, I will ask you, in accordance with the motto which heads your correspondence columns, "*Audi alteram partem*," to insert a few words from me as to a portion only of Dr. Miller's statements. I say nothing as to the action of the lady guardian therein mentioned nor to that of "the parson's [i.e., my] sister," nor to that of Miss Annie McCall, M.D. Bern, &c. The two former are away from home and the latter is engaged in practice at some distance from here. I would not pretend to give an opinion on a question of medical etiquette. But I have little doubt but that those ladies could give a somewhat different version of the circumstances from that given by Dr. Miller, and I may venture to say that I am somewhat surprised to read your editorial comment upon what is nothing more than an *ex parte* statement. What concerns me is this, Dr. Miller alleges that my parish nurse "persuaded" the patient "not to come into the Cottage Hospital, but to go to Euston road Hospital." Had she done so she would have made a grave departure from her instructions, which are to work under and with the medical men in the various cases which she visits. I therefore asked her the facts of the case and she positively declares to me (1) that she did *not* persuade the patient not to go into the Cottage Hospital, but, on the contrary, urged her to do so; (2) that she never said a word to her about the Euston-road Hospital at all, and (3) that on being accused by Dr. Miller on these two heads she denied to him that she had done what he accused her of. I should not have troubled you with this letter but for this one reason, that Dr. Miller's statement respecting the parish nurse, if uncontradicted, might greatly impair the very valuable work she is doing among my sick poor without cost or charge to them. I beg to remain, your obedient servant,

H. R. COOPER SMITH, D.D.,

May 19th, 1897. Vicar of Basingstoke.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Medico-Chirurgical Society.

THE last meeting for the present session was held on the 14th inst., the President, Dr. W. L. Reid, being in the chair. Dr. Walker Downie showed a man, sixty-six years of age, on whom he had successfully operated for Septic Thrombosis of the Right Lateral Sinus. The condition had succeeded a catarrh of the middle ear and was regarded as a sequela of an attack of influenza from which the patient had suffered. A feature of the case which attracted some comment was the very slight disturbance of temperature manifested by the patient before operation. In the experience of the majority of the speakers septic sinus thrombosis was accompanied by considerable waves of febrile temperature.—Dr. T. K. Dalziell showed a woman who for seven years had been a victim to Severe Facial Neuralgia affecting all the branches of the fifth but always commencing with a burning sensation at the angle of the mouth, where also there was distinct and localised tenderness on pressure. These symptoms had been completely relieved by excision of the long buccal nerve. The operation performed was the external one, and though it had left a well-marked scar this result had been discounted before the operation, which had been deliberately selected in preference to the operation from the buccal cavity, with its attendant septic risks. Dr. Dalziel also showed a boy, aged three and a half years, who had been born with an Imperforate Anus, a condition easily relieved at the time by the passage of a blunt instrument, but in whom subsequently such an amount of cicatricial tissue developed as to cause stricture of the bowel. There had been considerable difficulty in dealing with the case, and in the end the stricture had been excised by Kraske's operation, and with very good results. Dr. Dalziel also showed a boy who had suffered from Gangrene of the Lung, believed to be due to the entrance of some particles of toast into the air passages, and who had been treated successfully by excision of the gangrenous tissue.—Mr. H. E. Clark showed the brain removed post mortem from the body of a man on whom he had operated for Cerebral Tumour. The case in its earlier developments had been seen by Dr. T. K. Monro and by Dr. Alexander Robertson, and these gentlemen contributed the clinical history. The earlier symptoms were very obscure, being

Hosted by Google

limited to an occasional attack of vertigo and a sense of temporary numbness and weakness in the limbs of the left side. Subsequently twitchings were observed in the limbs, and on one occasion an attack of general convulsions. A family history of epilepsy to some extent confused the diagnosis, but in time headache, optic neuritis, Jacksonian spasms in the left limbs, taken with the other facts of the case, justified a conclusion of the existence of a tumour in the motor area of the right cerebral convolutions. It was decided to trephine the skull so as to gain access both to the arm and leg areas. This was done, but no tumour could be found. The bulging of the dura mater indicated the fact of undue intracranial pressure, but exploration of the brain tissue as far as this was possible was everywhere negative. At the post-mortem examination a considerable glio-sarcoma was found deeply situated in the superior parietal convolution. Mr. Clark doubted whether the tumour could have been removed under any circumstances, but pointed out that the practical surgical lesson from the case was that too much reliance must not be placed on the symptoms as indications of the precise seat of the tumour, and that in operating a large flap should be taken and if necessary numerous openings made in order to gain access to the whole motor region. Mr. Maylard supported this statement, and quoted his own experience where, in a patient with symptoms localising the tumour in the motor region, no tumour was found on trephining until a number of discs of bone were removed, and then a sarcoma was detected and successfully removed from the frontal lobe. The growth was entirely in front of the motor area, and the case therefore showed that motor disturbances did not necessarily mean direct pressure upon the motor convolutions.

Clinical Research Laboratory in Glasgow.

The directors of Anderson's College Medical School have adopted the proposal made by some members of the medical staff and have consented to the establishment of a clinical laboratory in the College buildings. It is intimated that the laboratory will be under the joint direction of Mr. R. M. Buchanan, M.B., C.M.Glasg., Professor of Forensic Medicine; Mr. R. Barclay Ness, M.B., C.M.Glasg., Professor of Therapeutics; and Mr. J. H. Teacher, M.B., C.M.Glasg.

Presentation to a Medical Man.

Mr. Robert Murdoch, Crown-street, Glasgow, has been presented with a number of medical books by the members of his ambulance class.

Provincial Infirmaries.

The directors of the Helensburgh Infirmary have received a communication from H.R.H. the Marchioness of Lorne intimating that Her Majesty the Queen has graciously consented to the use of the term "Victoria" as a title for the new infirmary. The Stirling Infirmary has received two separate donations, each of £1000, for the foundation of beds in the institution.

Aberdeen Ophthalmic Institution.

The resignation of Mr. J. McKenzie Davidson, M.B., C.M.Aberd., as ophthalmic surgeon at this institution led to an attempt to conjoin it with Aberdeen Royal Infirmary and Aberdeen Dispensary. The managers, however, resolved to continue it as a separate institution, and appointed Mr. A. Rudolf Galloway, M.A., M.B., C.M.Aberd., to succeed Dr. Davidson. Dr. Galloway has also been appointed medical officer to Aberdeen Asylum for the Blind, and Mr. Usher as ophthalmic surgeon at Aberdeen Royal Hospital for Sick Children, both in succession to Dr. Davidson, who is leaving Aberdeen. Dr. Davidson was, on the 18th inst., entertained by his professional brethren to a complimentary dinner in the Palace Hotel. Professor Ogston, Aberdeen University, presided, and in giving the toast of "Our Guest" paid a high tribute to the reputation which Dr. Davidson had made for himself in Aberdeen and the North of Scotland as an ophthalmic surgeon, and also as a teacher of ophthalmology in the medical school. Professor Stephenson, Aberdeen University, was croupier at the dinner.

Sanitary Inspectors' Congress.

This congress will take place in Aberdeen on June 17th and 18th. The corporation's public health committee will entertain the delegates to dinner, and has arranged for a drive to various places of interest in and near the city.

Aberdeen Hospital Jubilee Fund.

About £300 additional have been subscribed up to May 20th.

May 25th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mercer's Hospital, Dublin.

THE governors, at their last meeting, on May 18th, decided to permit applications for positions on the medical staff of this hospital to be received on or before June 18th, the election to take place on July 6th. It is impossible to say at present in what way the sudden and lamented death of Mr. Frederick Alcock Nixon, a senior member of the medical staff at Mercer's Hospital and an influential member of the board of governors, may influence matters. There will probably be a good many candidates for the position. Mr. J. D. McFeely, F.R.C.S.Irel., the assistant master at the Maternity Hospital, Holles-street, intends to apply specifically for the vacancy caused by Mr. Nixon's death.

Royal College of Surgeons in Ireland.

The annual election of officers will take place on Monday, June 7th. Mr. William Thomson and Mr. R. L. Swan will certainly be re-elected unopposed as president and vice-president respectively of the college. The vacancies on the Council will be contested. Mr. T. Myles of the Richmond Hospital and Dr. Cranny of Jarvis-street are candidates, while Mr. Murray and Mr. Sherlock come forward as representing the dental interest.

The Irish Medical Association.

The annual banquet of this association will take place on Monday, June 7th, at the Royal College of Surgeons. Numerous invitations have been issued by the President, Vice-president, and Council of the Association.

National Consumption Hospital, County Wicklow.

Earl Fitzwilliam has recently presented a donation of £1000 to the fund being raised for the National Hospital for Consumption for Ireland. Sir Henry Cochrane, the high sheriff for the county of Wicklow, in which the hospital is situated, has just subscribed £100.

Belfast Students and the Royal University of Ireland.

As the result of the recent honours examinations for the M.B. degree of the Royal University of Ireland Mr. Andrew L. M'Cully of Queen's College, Belfast, was awarded first-class and an exhibition of £40, and Mr. Walter B. Robertson, M.A., of Queen's College, Belfast, gained second-class, and qualified for the £25 prize. These were the only honours men. At the third examination in medicine of the Royal University of Ireland the only honours men were Mr. Graham, B.A., and Mr. Megard, B.A., of Belfast. They obtained second-class and exhibitions of £20.

Belfast Royal Hospital.

At the quarterly meeting of the general committee of the Royal Hospital, held on May 24th, Professor Sinclair, F.R.C.S.Eng., was appointed staff surgeon in place of Mr. Fagan (resigned), and Dr. Kirk was elected assistant surgeon, and Dr. McCutcheon house surgeon for the extern department. Hospital Saturday was on May 22nd, when upwards of £310 were collected, which is an increase on last year. There is a balance against the hospital of £2624 13*s.* 9*d.*

May 25th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Developments in Skiagraphy in Paris.

THE results of much working in many directions with the x rays are now communicated weekly to the different learned societies of Paris. At the Academy of Science MM. Sabrazès and Rivière recently announced that these rays have no action whatever on cultures of bacillus prodigiosus, not interfering with its chromogenic or other properties. The rays also were found not to have the least influence upon the action of white blood corpuscles or upon the phenomena of phagocytosis, while a frog's heart exposed to the rays for several hours appeared to undergo no alteration in movement. At another meeting of the Academy of Science MM. Springer and Serbanesco gave the results of

Hosted by Google

an investigation by the means of the rays into the processes of bone formation from cartilage and the pathological circumstances under which the development may be retarded. In myxœdema skiagraphy reveals that cartilage will remain a very long time without ossifying, and that when the patient is placed under the thyroid treatment development may go on up to the age of thirty-four years. In tuberculosis, hereditary or acquired, the cartilage persists and its ossification seems to be retarded. In hereditary syphilis the arrest of development appears due, on the other hand, to a precocious tendency to ossification. In the children of alcoholic subjects also the cartilage ossifies prematurely. To sum up, a great number of maladies modify the disposition of cartilage and its mode of ossification. Skiagraphy thus adds to our facilities for the study of faulty development a new and easily appreciable physical sign, and one which may be very useful for diagnosis and also from a therapeutical point of view.—At the Academy of Medicine M. Ollier showed recently by the x rays some of the results of bony repair after resections. From one patient M. Ollier had removed the astragalus and the skiagram showed that the bone had reproduced itself. In another patient operated upon for the results of acute osteo-myelitis, in which the astragalo-calcanean joint had been involved, M. Ollier removed the astragalus and gouged the calcaneus. Under the x rays it was seen that the calcaneus had reproduced itself and had formed a false joint with the lower end of the tibia. In another case the plate showed a white mark indicating a spot where bony formation had not taken place. In another case a bony graft was made in the middle of the tibia, filling a gap of eight centimetres in length which remained after a resection. The gap was shown to be nearly filled with reparative material, but to bring the approximating ends of the new tibia together a partial section of the peroneal muscles was necessary.—M. Bouchard at the same society communicated some results in the diagnosis of thoracic conditions arrived at by the new photography. He had been able to diagnose several cases of aortic disease. When the parts were normal he found that the pulsations of the aorta were not visible under skiagraphy, but when the valves were incompetent the skiagram showed clearly the systolic movement.—In a very interesting communication, also made to the Academy of Medicine, MM. Buguet and Gascard, professors at the School of Medicine of Rouen, have shown that the Roentgen rays are of great utility in the analysis of calculi, the approximate composition of which may now be ascertained without having recourse to the ordinary method of sawing or breaking them. By rendering the calculi transparent the rays reveal in their interior the foreign body, such as clots or solid fragments of some kind, constituting in most instances the nuclei upon which they are formed. In the case of calculi homogeneous in composition, the x rays have enabled their nature to be recognised according to their greater or less transparency. Biliary calculi are most transparent when they contain much cholesterine and comparatively little pigment. Uric acid calculi are in like manner most transparent when they contain only a small amount of calcium and magnesium salts, and ammoniaco-magnesium phosphate is of an opacity intermediate between the opacity of calcium salts and that of uric acid.

The Chair of Natural History at the Faculty of Medicine.

The Council of the Faculty of Medicine have deliberated concerning the chair of Natural History, which has now remained vacant for two years. Since the death of M. Baillon, the last occupant, new regulations with regard to medical study have somewhat modified the part played by ancillary science in the course of medical studies. Physics, chemistry, and natural history no longer form subjects of a compulsory course for the students at the Faculty of Medicine. Lectures in these subjects are given at the Faculty of Science, and after a preparatory examination in them the students are allowed to proceed to the Faculty of Medicine. The professorial chairs in these three sciences appeared thus destined to die out, as there were no longer any students to support them, but at the same time no one wished to suppress the existing professors. At the death of Professor Baillon it was agreed to do away with the chair of Natural History and there was a question of replacing it by a chair of "Parasitology," which chair has no place in the Faculty of Medicine. For two years the question has remained open and for two years the Faculty, economising to the extent of the salary of a professorship, made no haste to come to a decision. On the other hand, there was considerable feeling in favour of appointing M. Chantemesse as Professor of Natural History or of giving him a new chair of Micro-biology if it was founded. But the death of Professor Strauss having left vacant the chair of Experimental Pathology made an opening for Professor Chantemesse, who received the appointment some eight days ago. It is now decided that the chair of Natural History shall be maintained, and M. Blanchard will probably be nominated to the post in a few days. All parties will have their way in the end, as it is probable that M. Blanchard's course of lectures will deal entirely with Parasitology.

May 25th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The International Medical Congress in Moscow and State Recognition.

SCARCELY more than three months remain before the opening of the International Congress of Medicine and Surgery in Moscow. As the time approaches the committees entrusted with the preliminary arrangements are showing ever greater activity. The Organising Committee has just published a *résumé* of their work during the past eighteen months, and from this it may be seen that they have already obtained important results which should ensure the success of the Congress. Much of what is now published has already appeared in the columns of THE LANCET, but some is fresh and some will bear repetition. One of the most important statements the Committee is able to make is the fact that the Czar has taken the Congress under his patronage, and that he has consented to receive deputations from the various nationalities represented at the Congress. In this country that means much, and the Czar's gracious action will give the Congress an *éclat* and popularity which it could not otherwise have attained. It is probable that the reception will take place in St. Petersburg immediately after the close of the meetings in Moscow. The Russian Government has acted most liberally towards the Congress. It has increased its original grant of 50,000 roubles towards the expenses by an additional grant of 25,000. This makes the handsome total of 75,000 roubles, or about £8000 at the present exchange. In addition to this, as already announced in THE LANCET, the State has promised free railway tickets to members of the Congress from the frontier to Moscow and back. To Russian members similar free tickets will be granted from any part of the empire.

Moscow or Canada?

The Committee has made no public reference to the regrettable fact that two English scientific bodies have selected almost the same date for congresses to be held in Canada, but several members of the Committee have privately expressed their regret that this should be so, and are inclined to regard the action of these bodies as wanting in tact, if not in courtesy. It certainly is most unfortunate that the British Association and the British Medical Association in fixing the date for their meetings did not take into consideration the fact that the International Medical Congress had long ago been fixed for the latter half of August. Some Englishmen would probably have wished to go both to Moscow and to Canada, but this is impossible under the present arrangements, and it is certain that the coinciding congresses in the two countries will mutually act unfavourably in diminishing the numbers of Englishmen attending them. On the score of cost it seems probable that a visit to Moscow will be very much less expensive than one to Canada. From the description of the routes to Moscow recently published by the English Committee, and re-printed in full in THE LANCET,[1] it will be clear that, whichever of the interesting routes there described be chosen, the travelling expenses of the whole tour will be only from £10 to £15, and that the total expenses need in no case exceed £25 or £30. Few

[1] THE LANCET, April 24th, 1897, p. 1168.

Hosted by Google

capitals are more interesting historically, and none are more beautiful than Moscow; and as, whatever route be taken, the traveller must, in addition, see one or more of the following towns—Berlin, Warsaw, Smolensk, St. Petersburg, Helsingfors, Stockholm, Gothenburg, Copenhagen (to mention only the more important), it is clear that a cheaper or more attractive month's holiday could not be conceived. It is probable, therefore, that with many who may have hesitated between the attractions of Canada and Moscow, the latter will carry the day. Already large numbers of Americans and a considerable number of Englishmen have joined the Russian Congress. The Executive Committee has requested all intending members to send in their names and subscriptions early. Forms of inscription may be obtained from the Secretary of the English Committee, Mr. G. H. Makins (47, Charles-street, Berkeley-square, W.). It is only necessary to fill up the form and enclose a foreign postal order for 1 guinea (or 25 francs or 10 roubles) and post it; the form is fully addressed. It is advisable to register the letter in case of loss.

Congress Literature.

The Executive Committee have in preparation a number of guides and *brochures* for presentation to each member of the Congress. A general guide to Moscow, a guide to its medical institutions, a description of the great University Clinique, and a full account of *Zemskaia Meditzina* (or Medicine of the *Zemstvos*—i.e., the system of free medical aid provided for the peasants throughout the country), are the most important of these. Dr. Neiding is also preparing a historical description of the Russian medical societies.

The Sectional Programmes and Transactions.

The programmes of the sections are now nearly ready and will in a very short time be issued in one pamphlet. The transactions of the Congress will, it is expected, fill from 200 to 250 "sheets" of paper. Copies will be sent free to every member of the Congress.

Orators and Orations.

The following is the list of orators selected by the Committee and the titles of their orations, which will be read in the general meetings of the Congress: Professor Danilevski (of Khartof) on "The Action of Electric Rays on the Animal Organism at a Distance"; Professor Lukianof (of St. Petersburg) on a subject not yet stated; Professor Krafft Ebing (of Vienna) on "The Etiology of Progressive Paralysis"; Professor Senn (of Chicago) on "The Diagnosis and Surgical Treatment of Acute Forms of Peritonitis"; Professor Lombroso (of Turin) on "New Horizons in Psychiatry"; Professor Leyden (of Berlin) on "The Present Modes of Treating Consumptive Patients and their State Control"; Dr. Lauder Brunton (of London) on "The Relationship between Physiology, Pharmacology, Pathology, and Clinical Medicine"; Professor Robert (of Barcelona) on a subject not yet stated; Professor Herzen (of Lausanne) on "The Significance of Physiological Psychology for Medical Education." Professor Virchow (of Berlin) and Professor Roux (of Paris) have also been invited to read papers, but their replies have not yet been received.

Accommodation for Members of the Congress.

Nothing has yet been finally arranged as to the accommodation of members of the Congress in Moscow. Some fifty medical men practising in the city have offered to receive foreign members as guests for the period of the Congress. The Committee find that they can count upon 700 beds at hotels and 1600 in furnished apartments as being available at the time. They hope to come to some arrangement with the principal hotel proprietors, who may offer special terms if a sufficient number of visitors be guaranteed It is proposed also to print tickets with plans and information about rooms and tariff, to be given to each member of the Congress as he arrives at the terminus in Moscow.

A Congress Postponed.

The Tenth Conference of Naturalists and Medical Practitioners, which was to have been held in August this year in Kief, has been postponed to August, 1898, in consequence of the first date clashing with that of the International Medical Congress in Moscow.

St. Petersburg, May 3rd (15th), 1897.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Scarlet Fever.

IT is well known that scarlet fever in the East is not only not the scourge it is in Europe, but is extremely rare both in Asia and in Africa. In Egypt there are no reliable records of its occurrence in any epidemic form, but since the English occupation there have been several times a few sporadic cases, which have not spread either to the English residents or to the native population. This winter there have been seven cases among the children of British soldiers occurring in six families. There is little doubt that the first case is responsible for the spread to the others, and it was therefore thought advisable to close the school in barracks, which was attended by fifty or sixty children, and since this was done there have been no fresh cases. The first case occurred about Christmas time, and it was thought that perhaps the infection might have arrived by post from England in a letter, doll, or clothing. But the parents of the child denied all communication with Europe even by letter post, and the introduction of the poison must remain a mystery. Equally impossible has it been on former occasions to discover whence the infection has arrived. It is worth pointing out that it is only during the winter months that sporadic scarlet fever has been observed among the English, while it is said to be quite unknown among the Egyptians.

Prison Department.

Crookshank Pasha has just issued a farewell report of his administration. It appears that the number of prisoners is on the increase, for on Dec. 31st, 1895, there were 8800 inmates, while on the last day of 1896 there were 10,500 male prisoners, besides 415 women. High praise is given to the medical officers, all of whom are Egyptians. During the late cholera 17 prisons were attacked, and there were 70 deaths from cholera, besides 131 deaths during the year from other causes. Two directors of provincial prisons died from cholera at Assiout and Mansurah, one of them being a medical officer.

Armenian Refugees.

The Egyptian Government has done what it can to prevent any great influx of Armenian exiles from the Turkish provinces, but there have been during the winter from 500 to 600 in Alexandria, besides about 300 who have found their way to Cairo. They are for the most part small shopkeepers or clerks and their families, unfitted for work anywhere, unable to talk Arabic, unwilling to take small salaries and coarse food, and afraid of the Soudanese climate. However, a few of them have been sent to work on the railway in Upper Egypt. In Cairo the Government has so far declined the responsibility of giving them shelter, and the charitable committee is unable to spend more on them than the £50 a month which their food costs, consisting chiefly of bread, soup, and vegetables. About 250 men, women, and children are crowded into some insanitary houses near the Armenian church, which is, unfortunately, in one of the densely populated quarters of the town. In one house there were at my visit thirty-five persons sleeping in a corridor with their beds touching each other, twenty-one were counted in a small room, and in another there were seven women, one of whom had recently been confined. Her baby and another were hanging in hammocks slung from the bedposts. The empty rooms were pervaded with the animal odour common to overcrowding, and the latrines were as primitive as might be expected. Some of the refugees are tuberculous and there have been a few cases of measles and chicken-pox among them, but fortunately as yet no typhus fever. Some English amateur theatrical performances lately provided over £300 for these unfortunate exiles.

Cairo, May 10th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Objectionable Advertising.

IT is my unpleasant task to draw attention to a form of advertisement which is regarded—I may say universally—by members of the medical profession in this colony as highly

Hosted by Google

objectionable, more especially as the medical profession in New Zealand are most anxious to preserve the distinction in this colony between the methods of a trade and those of a profession and to observe the rules of professional conduct which have been sanctioned from Linacre's down to the present time. The standard of the profession must be strictly kept up and rigidly maintained by each and every local branch in New Zealand. F. Wallace Mackenzie, M.B., M.S. (University of Edinburgh), practising in Wellington as an eye and ear specialist, has received for some years past almost the entire share of attention and courtesy (as far as his specialty is concerned at least) from, not only medical practitioners in Wellington, but also from those of his professional brethren in other parts of the colony, but more especially from those residing in Napier, Wanganui, Taranaki, and the east and west coast of the North Island generally. In this respect, having regard to his practice, Dr. Mackenzie can have no possible ground for complaint. Now the only unpleasant transaction that occurred during the Inter-colonial Medical Congress week, held at Dunedin in February, 1896—a gathering of medical men which will be remembered for years to come with the greatest satisfaction by all those who were fortunate enough to be able to be present—was a complaint by the members of the Napier Branch of the New Zealand Medical Association against Dr. F. Wallace Mackenzie, of Wellington, for advertising in their local paper by announcing himself in the following manner: "That Dr. F. Wallace Mackenzie, of Wellington, would arrive in Napier on such and such a day, and could be consulted at such and such a pharmacy." Now no notice of motion had been tabled, but in reply to Dr. Milne-Thomson (who acted as delegate for the Napier Branch) the president of the meeting stated that he was willing and able in the circumstances to give a decision on the interpretation of a rule. In this way Dr. Milne-Thomson was enabled to bring the subject up for a ruling. The delegate acting for the Napier Branch read the advertisement in the *Hawke's Bay Herald* announcing Dr. Mackenzie's intention to visit Napier on certain dates, and stated that what the Napier Branch maintained was "that any medical man practising in New Zealand should not be allowed to advertise his intention to visit a neighbouring town or district, and that this particular advertisement was contrary to the rules of the Medical Association." This rule had been passed at the previous Auckland meeting. A discussion then ensued as to whether this was or was not a rule of the Association. The President (Dr. Lindo Ferguson of Dunedin) replied: "That it was certainly a rule which had been adopted by the Auckland meeting, which had adopted a very high standard, and it seemed to him that there could be no argument about the decision. An advertisement was permissible to a person carrying on a practice for two months in the town or county in which he proposed to practise and no more. The form of the advertisement was absolutely laid down, and the practitioner was not allowed even to insert his hours of consultation or his qualification, and that it was not necessary for the Council to express any further opinion. The subject was so clear that argument was out of the question." The medical men practising in Napier felt that Dr. Mackenzie had no right to announce himself in this manner in the locality of Napier, where a specialist in diseases of the eye and ear, who has gained the confidence of his medical brethren, resides. Now, after Dr. Mackenzie's experiences in connexion with the Napier branch's strictures on his advertising methods I should have thought that he would not allow himself to be placed in such an equivocal position again. This does not appear, however, to be the case, as the following advertisement, which appeared in the *Wanganui Herald* during the end of February and the beginning of March, 1897, indicates:—

NOTICE.

DR. F. WALLACE MACKENZIE has removed from 139, Upper Willis Street to 162, Upper Willis Street, Wellington, opposite St. Peter's Church.

Dr. F. Wallace Mackenzie, the well-known specialist, of Wellington, has removed from 139, Upper Willis Street. His present address is 162, Upper Willis Street, opposite St. Peter's Church, Wellington.

Dr. Mackenzie purposes being in Wanganui on the 16th, and will stay at Chavannes' Hotel.

In nothing is the tradition of medical conduct more particular than in reference to the treatment of medical brethren. There is no sin more gross in medical ethics than the combination of medical men formed with the object of "running off the road" by disparaging and harsh statements the professional skill and personal character of a brother practitioner, and I have no desire to unduly hurt Dr. Mackenzie's feelings, but he must be taught to observe our honourable traditions and maintain them. The above advertisement having been inserted in the *Wanganui Herald* for ten days or so, it was decided to call a meeting of all the members of the profession practising in Wanganui to discuss Dr. Mackenzie's attitude. It was then unanimously decided that the following communication should be forwarded to the honorary secretary of the Wellington branch of the New Zealand Medical Association for their consideration, and a copy of it forwarded to Dr. Mackenzie.

Wanganui, March 6th, 1897.

The Hon. Secretary, Wellington Branch of the New Zealand Medical Association.

SIR,—We beg to draw your attention to a notice which is appearing in the *Wanganui Herald* and we forward you a copy of the newspaper containing the same [notice as already printed above]. We beg to submit that the insertion of the above notice in a Wanganui paper, over a hundred miles from the residence of Dr. Mackenzie, is uncalled for, and not in accordance with the best traditions of the profession.

Signed by all the members of the medical profession practising in Wanganui.

The Wanganui society's honorary secretary received the following letter in reply from Dr. Mackenzie:—

Mr. Hatherly. Wellington, March 9th, 1897.

DEAR SIR,—The Wellington branch of the association was wound up at the February meeting. The branch had a rule *re* advertising to the effect that a member on changing his address might advertise the fact in the papers in the district in which he is practising for a period of fourteen days. My advertisement is strictly in accordance with that rule; the district in which I am practising is the Wellington Provincial District, which to me for practice far exceeds the limits of the province itself. Kindly inform those who were anxious for enlightenment that, firstly, my innocent little notice was for the benefit of my patients solely; I do not require to advertise myself—my friends do that. Secondly, the advertisement was called for by a local appearing in the *N.Z. Graphic* to the effect that I was giving up practice in Wellington and going to settle in Picton, the fact being that I had merely moved into a new house without advertising the fact of my removal. Thirdly, if the mortmain of tradition is going to lay its icy grasp on the profession here, if the profession is to be guided by the traditions of the past rather than by the good sense of the present, I am sorry for it. Since you do not like the ad. it will not appear any more.

Yours faithfully,

F. WALLACE MACKENZIE.

Dr. Mackenzie's ideas concerning the "icy grasp of tradition" are unique. I trust that this will be the last occasion upon which I shall have to criticise in such a case. It is a most unpleasant task, but it is one that has to be performed when the occasion demands it.

Cancer in New Zealand.

By a recent return of the Registrar-General the deaths from cancer during the year 1896 amounted to 389, of which number 205 were males and 184 females, the rate of mortality per 10,000 living being equal to 5·50. The apparent increase, however, of the deaths shown in the table below is in all probability due to a more advanced care in diagnosis and a more accurate return as shown in the death certificates than had existed during the previous decade. The total deaths from all causes in the colony during the year 1896 totalled 6432. By these figures, then, it is shown that the percentage of deaths due to malignant disease is equivalent to 6 per cent. on the whole death-rate. The following table shows the number of deaths from cancer in every 10,000:—

Year.	New Zealand.	England.
1881	2·69	5·20
1886	3·63	5·90
1891	4·68	6·92
1896	5·50	7·13 (1894)

New Zealand Annual Medical Conference.

The 1897 Conference of the members of the medical profession was held this year at Nelson on March 9th and following days, under the able presidency of Dr. Cleghorn, who gave a most carefully prepared and practical address treating for the most part on the club question and on general matters in which the profession and the public were mutually concerned. I hope to forward a complete account of the proceedings by the next mail. The meeting was a great success from a scientific and social point of view, and the visitors from various parts of the colony were most hospitably entertained by their professional brethren practising at Nelson.

Obituary.

GEORGE CHAPMAN BRIGGS, M.B. LOND., M.R.C.S. ENG., L.S.A.

WE regret to have to record the death of Dr. G. C. Briggs, of Harrow-on-the-Hill, which occurred on May 5th from diabetic coma. Born in 1847 at Burgh-le-Marsh, in Lincolnshire, his father farming his own land in that county, he was educated at Uppingham School under the well-known Dr. Thring, and after reaching the sixth form he left to commence his studies for the medical profession by serving an apprenticeship to his uncle, the late Mr. Frederick Fawssitt, F.R.C.S., of Wisbech. In 1867 he became a matriculated student of King's College, London, and obtained a junior scholarship, two years later the Warneford scholarship, and the senior scholarship in 1871. He was also a prizeman in obstetrics, chemistry, and other subjects. After qualifying in 1871 he held the post of resident accoucheur in King's College Hospital and graduated M.B. Lond. in 1874. In the same year he became the junior partner in the firm of Bridgwater and Tonge at Harrow-on-the-Hill, and at the time of his death was the senior member of the firm of Briggs, Bindloss, and Lambert. For the last ten years Dr. Briggs has acted as chief medical officer to Harrow School in addition to other public appointments, such as Poor-law medical officer and public vaccinator to the Harrow district. He was also a member of the Council of the Medical Officers of Schools Association. Dr. Briggs had no special pursuits or hobbies outside his profession, and may be said to have thrown the whole of his energies into his work. Possessed of great natural ability, and of a genial and kindly disposition, he was beloved and esteemed both by his patients and by all who knew him, whether rich or poor, and although for the last six years he was aware that he was the subject of a dangerous and debilitating disease, he worked on cheerfully and with an unselfish devotion, placing the interests and welfare of his patients before everything. A few weeks ago he was attacked with middle ear disease and, diabetic coma supervening, the end soon came.

He married in 1879 the daughter of Mr. H. G. Cooke, of Alverstoke, near Gosport, Hants, and the sister of Dr. Marriott Cooke, his friend and fellow-student at King's, who is now the superintendent of the Worcester County Asylum. Mrs. Briggs survives him, as do two sons, who are now studying at Harrow School. His body was laid to rest in the churchyard adjoining the old parish church at Harrow, and was followed to the grave by many sorrowing relations and friends.

EVAN DAVIES, L.R.C.P. & S. EDIN., &c.

THE neighbourhood of Maesteg, Glamorganshire heard with much regret of the death of Mr. Evan Davies, which took place on May 18th under sad circumstances. Mr. Davies was thrown from his horse on the preceding day, whilst returning from visiting a patient, and sustained a fracture of the skull, his injuries soon proving fatal. The deceased received his medical education at the Glasgow University and the Western Infirmary, Glasgow, and obtained the qualifications of L.R.C.P. & S. Edin., L.F.P.S. and L.M. Glasg., in 1892. He was surgeon to North's Navigation Collieries, and formerly held the appointment of medical officer of health for the Maesteg Urban District. He was only thirty years of age at the time of his death, and was extremely popular in the district. On May 22nd he was to have been presented with a gold pendant, bearing a suitable inscription by the members of the St. John Ambulance Class, of which he was the honorary instructor. The funeral, which was a public one, was largely attended.

DEATHS OF EMINENT FOREIGN MEDICAL MEN. — The deaths of the following eminent medical men are announced:—Dr. Charles Dubreuilh, formerly surgeon to the Bordeaux Hospitals.—Dr. Adolfo Moreno Pozo, Professor of Topographical Anatomy and of Operative Medicine in the University of Madrid.—Dr. H. Sünder y Rodiguez, a well-known Madrid surgeon.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE sixty-second session of the General Council of Medical Education and Registration was opened on Tuesday, May 25th, by the President, Sir Richard Quain.

Sir Richard Quain delivered his address with an energy surprising to those with knowledge of the grave illness through which he has lately passed and to which he alluded with some feeling. It may safely be said that scarcely any other man in London would have attempted such an undertaking in the same circumstances, and with equal certainty it may be affirmed that Sir Richard Quain would not have allowed any patient of his to do so. Either he has more indulgent advisers than his patients have, or he is, as one of his distinguished colleagues said, a law unto himself.

The new Pharmacopœia begins to loom in the distance. Large parcels in brown paper might be seen before each member of the Council on the first day of the session which turned out to be proofs of the work—in a very imperfect state, of course. It is expected, as the President said, to be completed by the November meeting. Meanwhile, its present state of forwardness must be consolatory to Sir Richard Quain, who has always taken great interest in this part of the Council's work and regards the pilotage of the new edition as his chief work for the Council.

The varied character of the business of the Council will be best gathered from the opening address of the President and the forecast in THE LANCET of last week. The most noticeable event of consequence in the proceedings up to the time of our writing is the resolution of the Council to act on the direction of the Privy Council in the matter of the appointment of Surgical Examiners for the Apothecaries' Hall of Dublin. Our readers will doubtless study for themselves the statement on this subject submitted to the General Medical Council by its legal advisers. It contains a gentle—we will not say rebuke but—reminder that the course taken by the General Medical Council was never favoured by its legal advisers. They have been throughout of opinion that in the circumstances the Council had no option but to appoint surgical examiners to a medical corporation that had failed to find in its own part of the kingdom a surgical corporation to act in conjunction with it. The General Medical Council, construing the words "if it see fit" in the common-sense way in which all men but lawyers construe them thought it had a discretion. It has been disabused, and now accepts the legal reading with a fair amount of grace and with the comforting assurance of the lawyers that whatever happens the Council is relieved of all responsibility.

The examiners whom it will now appoint will be not merely examiners but inspectors, for it will be their duty under Clause 2 of Section 5 of the Act of 1886 to secure at the examinations the maintenance of such standard of proficiency as is required by the Act. The whole incident is a very noticeable one in the profession. It not only helps the General Medical Council to realise that in the last result the Privy Council is a *superior medical* authority, having power to do that which the Council fails to do in the construction or continuance of the medical institutions of the country, but it will bring home to the medical profession its subjection to law—or, rather, to lawyers and their construction of law.

Hosted by Google

The Privy Council has shown on the whole consideration to the General Medical Council while maintaining a strict and technically legal view of the Act. Meantime the Apothecaries' Hall of Ireland has a new lease of life and a new opportunity of showing that (as the Duke of Devonshire, with very doubtful grounds, seemed to think) it is really the gate and entrance of a considerable number of the general practitioners of Ireland. Everybody will wish and believe that in this new lease of life it may have every fair-play at the hands of the General Medical Council.

The subject of the Midwives Bill came transiently before the Council at its first sitting. A tendency to warmth on the very mention of the subject was creditably restrained, and all parties accepted a motion by Dr. McVail that inquiry be made as to whether the Government still desired the Council to consider the Bill this session. The Government, in referring all such Bills to the General Medical Council recognises the medical importance of the question and imposes on the Council the duty of attention.

The Council on Thursday, after approving the minutes of Wednesday's proceedings, engaged in the consideration of a number of penal cases. Our report of what was done will be published in next week's issue. The Council adopted the form of the address to be presented to Her Majesty the Queen on the occasion of the completion of the sixtieth year of her reign, and they received a statement from the President with regard to the deputation on the subject of death certification to the President of the Local Government Board. He said the deputation would, among other things, press upon the President the registration of undertakers and the separation of deaths from births and marriages.

It was agreed by the Council to make representations to the Privy Council with regard to a proposed law in Italy modifying the law of the country which permits foreign medical men to practise there.

The report of the Pharmacopœia Committee was also brought up on Thursday morning and adopted.

TUESDAY, MAY 25TH.

THE sixty-second session of the General Council of Medical Education and Registration was opened to-day in the offices of the Council, Oxford-street, London. To the great satisfaction of all the members Sir Richard Quain was able to take his accustomed place in the chair and to open the session as usual with a short presidential address.

The Recently Elected Direct Representatives.

Dr. R. R. Rentoul, Mr. George Brown, and Dr. Glover, the new Direct Representatives for England, attended, and Dr. Glover introduced to the President his two colleagues. Dr. Bruce, the Direct Representative of the Scottish practitioners, was also in his place.

Introduction of Professor Robert William Reid.

Sir WILLIAM TURNER introduced Professor Robert William Reid, the successor of Dr. Angus Fraser in the representation of the University of Aberdeen.

The President's Address.

The PRESIDENT commenced his address with some words of welcome to the new members and a sympathetic reference to the failing health and consequent retirement of Mr. W. J. C. Miller, the Registrar of the Council, and continuing said:—

Since our last session we have completed the purchase of the remaining (leasehold) interest of the Office of Works in our premises, and those of the tenant in Hanover-square. The purchase of the freehold and leasehold of the premises, together with all the expenses incidental thereto and to the re-building and alterations which have been undertaken, have cost the Council £22,506 13*s.* 10*d.*, an amount which has been advanced by the English Branch Council at 3 per cent. interest. We may therefore consider that we hold both the premises at a rent of £675 per annum. From this sum we have to deduct £250 per annum paid for 16, Hanover-square, leaving our rental at £425 compared with a former nominal rental of £300 which was paid to the Office of Works for the unaltered premises. Our additional rental, therefore, will amount to £125 per annum for eight years, when the whole premises in Hanover-square and Oxford-street will be at our own disposal. We have taken such action as was possible in the matter of the registration of deaths. The Council's resolution of Nov. 27th, 1896, in regard to death certification was formally communicated to the Registrar-General on Dec. 3rd, 1896. He answered to the effect that so far as the law was concerned he was unable to find any irregularity in the conduct of the registrar of Hetton-le-Hole in accepting the informal "statement from the unregistered—perhaps unqualified—attendant as part of the information of the informant." Such being the answer of the Registrar-General, we had, in accordance with the direction of the Council, to seek an interview with the President of the Local Government Board. Various circumstances, including the illness of the President of the Board, and the absence abroad on important official business of Dr. Thorne Thorne, have rendered it hitherto impossible to obtain an interview with the right honourable gentleman. In the meantime an important statement has been prepared, with the assistance of the legal advisers of the Council, for submission to him, and an early opportunity will be sought of presenting it by a deputation. The Executive Committee has prepared a Report on the Disciplinary Powers of the Licensing Bodies—a matter which was referred back to it by the General Council on Nov. 24th, 1896. It will be seen that two bodies—viz., the Victoria University and the University of Durham—have taken steps in the direction of obtaining modifications of their Charters, which would give them penal powers over their graduates. The University of Cambridge has already obtained, and exercised, such powers, and the Royal University of Ireland is said to be engaged in obtaining them. It is much to be regretted that the Scottish Universities still find difficulty in moving in the matter. I have very great satisfaction in announcing that the material for the British Pharmacopœia has been completed, and will be placed in the hands of the Council during the present session. This material has been most thoroughly revised by the eminent experts who were invited to assist in the revision, and who have done so with great care. The most hearty thanks of the Council are due to these gentlemen for their services, to the Pharmacopœia Committee of the Pharmaceutical Society, and also to the Pharmacopœia Committee of the Council. We have recently taken advantage of the introduction into Parliament of a measure for the regulation of the payment of the Metropolitan Police to propose the insertion of a clause, giving the penalties inflicted in all cases under the Medical Acts to the treasurers of the General Medical Council, so as to fulfil the intention of the provisions of the Medical Act, 1858, Section 42. It will be remembered that in London the penalties go to the police, and that claims to these penalties have arisen also—outside the Metropolis—under certain local Acts.

[Sir Richard Quain here mentioned that the business before the Council would include the decision and direction of the Privy Council with reference to the appeal of the Apothecaries' Hall of Dublin, the question of the Medical Aid Associations, a revised Standing Order Dealing with Penal Removals, and Reports by the Dental Education, the Examination, and other committees. He continued:]

A Bill for the Registration of Midwives (entitled the "Midwives Registration Bill") was forwarded from the Privy Council Office on Feb. 16th ult., with a request that the General Council would favour their lordships with an opinion thereon, and the Executive Committee, at its meeting on Feb. 22nd, directed that the resolutions passed by the Council on Nov. 29th, 1889, and June 5th, 1895, should be forwarded to the Privy Council. Dr. Rentoul has informed me that he had prepared a Bill which he was desirous of submitting to the Council on the subject of Midwives, but I pointed out to him the very decided language used by the Council on Nov. 29th, 1889, on the subject of not interfering with legislation for Midwives. The closer we keep within the paths marked out for us by our Statutory Powers, the less trouble we shall have, and the more satisfactory will be the result of our proceedings.

Hosted by Google

Sir WILLIAM TURNER moved that the President be thanked for his address and be requested to allow it to be entered on the minutes. He ventured to say that they ought not to regard this as a mere formal motion. They all knew the very severe operation that he (the President) had to undergo not many weeks ago, and they were glad to think that he had so successfully recovered from it and that he felt able to preside over them on this occasion.

Mr. BRYANT, seconding this motion, desired to echo what Sir William Turner had said.

The PRESIDENT thanked the Council for their kindness, and said that whilst he was spared to live he would do his best for the Council.

Business Committee.

Mr. ALLEN, who, in the absence of Mr. Miller, acted as clerk, intimated that Mr. Bryant, Dr. MacAlister, Dr. Moore, and Sir William Turner had been nominated to the Business Committee.

Mr. GEORGE BROWN thought that there should be one of the Direct Representatives on this committee, seeing that there were matters coming before the Council of very great interest to general practitioners. Perhaps Mr. Bryant would see his way to retire in favour of Dr. Glover.

The PRESIDENT said that there was no order of this kind. These gentlemen were selected by reason of their knowledge of the business of the Council and their experience, and they were the best men that could be named for the purpose.

Dr. BRUCE said that, speaking as one of the Direct Representatives, he thought they could not get a better man on the committee than Dr. MacAlister.

The committee as proposed was thereupon agreed to.

The Queen's Jubilee.

The PRESIDENT moved that a committee be appointed to prepare an appropriate address to Her Majesty on the completion of the sixtieth year of her reign. He was sure it would be the spontaneous wish of the Council that they should present an address on this occasion.

The motion was at once carried with acclamation, as was also a motion to expend a suitable sum upon illuminations on Jubilee Day.

Results of Examinations.

Mr. ALLEN presented a number of tabulated statements showing the results of various examinations in 1896.

Dr. HERON WATSON moved a vote of thanks, which was seconded by Dr. THORNE THORNE, to certain officials who had supplied information for the statements.

Dr. ATTHILL said he was anxious to know whether it would be possible to obtain information which would enable them to trace the candidates who had failed in any particular subject. They had received a circular in Ireland stating that a Licentiate of his College had failed in spelling, and he thought it most desirable that they should know where such a Licentiate received his certificate of preliminary education.

Mr. ALLEN said that after the last meeting of the Executive Committee he had applied to the Navy Department asking for the names of candidates, and they wrote back expressing regret that they could not supply them.

Mr. GEORGE BROWN said it was a great scandal that men should be admitted into the medical profession who did not understand the elementary rules of the English language in regard to spelling. From these returns he found men were passed with 26·7 per cent. of marks, 28·3 per cent., 36·6 per cent. and so on, very many being under 50 per cent.

Sir DYCE DUCKWORTH said that this question had been carefully considered by the Naval Medical Examining Body, of which he was a member. As a Board they could do nothing, for they examined numbers not men, but they found abundant evidence of defective preliminary education. It was quite manifest that men were allowed to pass who were very deficient in general education, and he thought it was the duty of this Council to call upon all the examining bodies to furnish them with the means of getting information about them. It had been proposed that this might be done by insisting that every candidate for a diploma when he registered himself as a student, should put alongside his name the body before which he passed his preliminary examination. In that way it would be possible to trace him. The examining bodies appeared to wash their hands of this matter entirely. It was true, of course, that very often many of these men who could not spell and knew nothing about punctuation and could not construct a grammatical sentence were exceedingly well up in their professional work. At the same time he thought they should get at the root of this matter and find who it was who was responsible for the admission of men of inadequate education into the profession.

Dr. BATTY TUKE reminded the Council of what had been done by them last year, and said that the Education Committee was carefully considering how the standard of preliminary education could be raised and would report next November.

Dr. HERON WATSON said that this debate could have no relevance to the motion before the Council.

Dr. ATTHILL said he would be quite willing to postpone it.

Dr. MACALISTER suggested that the Council might furnish the Navy and the Army Board with a copy of the Students' Register, and they might communicate with the Council with reference to particular candidates without mentioning any names.

The motion was then adopted.

The Application of the Apothecaries' Hall of Dublin.

Mr. ALLEN read the order of the Privy Council directing this Council to appoint assistant examiners in surgery in the Medical Act of 1886 for the purpose of qualifying examinations to be held by the Apothecaries' Hall of Dublin.

Mr. ALLEN also read the following statement by the Council's legal advisers, viz. :—

Understanding that some members of the Medical Council wish for further information respecting the procedure of the Council, and the result of the decision of the Privy Council in the Apothecaries' Hall, Dublin, case, the legal advisers of the Medical Council submit the following statement:—

1. After the combination of the Royal College of Surgeons with the Apothecaries' Hall had come to an end, the Apothecaries' Hall reported to the Medical Council their inability to combine with any other Corporation, and applied to the Medical Council to appoint assistant examiners in accordance with Section 5 of the Medical Act, 1886. On the consideration by the Medical Council of the application of the Apothecaries' Hall, the opinion of the Council's legal advisers, as expressed to the Council, was that the grounds on which it was proposed to refuse the application of the Hall involved in effect an exercise by the Medical Council of a jurisdiction which properly belonged to the Privy Council alone.

2. The Medical Council having declined to accede to the application of the Hall, that body applied to the Privy Council, who referred the matter back to the Medical Council for reconsideration. The Medical Council thereupon gave the Apothecaries' Hall a further opportunity of trying to effect the necessary combination; but the Hall was unable to effect it and reported its inability to the Medical Council, and again applied for the appointment of examiners.

3. The Medical Council having again refused to appoint examiners, the hearing before the Privy Council was resumed, and the Privy Council came practically to the conclusion that the procedure adopted by the Medical Council in refusing to appoint assistant examiners for the Hall was not a regular exercise by the Medical Council of their jurisdiction, the power to deprive a body of its right to hold a qualifying examination being vested solely in the Privy Council. The Privy Council accordingly by their decision directed the Medical Council to appoint assistant examiners in surgery.

4. The direction given by the Privy Council relieves the Medical Council from all responsibility in the matter.

5. The Privy Council, besides being the highest judicial tribunal in the United Kingdom, is the tribunal on whom Parliament has conferred a special and plenary authority to act as the lords of the Council think fit in such a matter as an application by one of the medical corporations for the appointment of assistant examiners. (Act of 1886, Section 19.)

6. The legal advisers of the Medical Council are of opinion that the Privy Council has not by its direction to the Medical Council intended to interfere, or, in fact, interfered, with the Medical Council in the exercise by the Medical Council of its statutory jurisdiction, but that the view adopted by the Privy Council has been that the Medical Council had in its refusal to accede to the application of the Hall in effect taken upon itself to exercise a jurisdiction which belonged to the Privy Council alone and not to the Medical Council.

7. The legal advisers of the Medical Council respectfully suggest in these circumstances that the direction of the Privy Council should be acted on without comment.

Mr. ALLEN further read a letter from the secretary of the Apothecaries' Hall of Dublin, laying before the Council the names of two gentlemen who were proposed as assistant examiners in surgery.

Mr. TICHBORNE said that to put the matter in form he would move the following motion—

"That, subject to the orders of the Council, Messieurs—

"L. Hepenstal Ormsby, M.D., F.R.C.S., Surgeon to the Meath Hospital and County of Dublin Infirmary; Surgeon to the Children's Hospital, Dublin; and ex-Examiner in Surgery, Royal College of Surgeons, Ireland;

"Frederick Conway Dwyer, M.D., B. Ch. Univ. Dublin; Sen. Mod. and Gold Medal in Exper. Science, Ex. Med. Schol., T.C.D., Surgeon, Jervis-street Hospital; Demonstrator of Anatomy, Royal College of Surgeons, Ireland;

"be appointed by the Council to be Surgical Examiners to assist the Apothecaries' Hall of Ireland in the conduct of its qualifying examinations."

These names were the names laid before the Council in the letter of the secretary of the Hall, and were the names of gentlemen well qualified to act as examiners.

Hosted by Google

Sir JOHN BANKS seconded the motion, saying that he knew the two gentlemen to be highly fit and proper persons to be engaged in this work.

Mr. BRYANT said that this was a subject which he thought would be better discussed by a small committee, and he begged to move as an amendment: "That the Council act on the direction of the Privy Council and appoint a committee to nominate the assistant examiners, to recommend the amount of the remuneration to be attached to the office, and to report to the Council during the present session."

Dr. BATTY TUKE seconded this amendment.

Dr. THORNE THORNE said it was important for the Council to remember that the duty of these assistant examiners would be to secure at the examinations the maintenance of such standard of proficiency in surgery as was required.

Sir DYCE DUCKWORTH said he should like to make a few remarks upon the statement of the legal advisers. For many years the Council had been doing this work of inspecting examinations, and he, as chairman of the Examination Committee, felt very keenly on the matter. As the result of these inspections the Apothecaries' Hall was reported again and again as inadequate, and the Council took definite action upon that. The Council had done its duty most carefully and prudently. Every step was taken by the direction, and under the eye, and by the advice, of their legal advisers, and therefore he found great difficulty when he read this statement which had been put before the Council. What else could they do than they had been advised to do? If they were told that everything turned upon these words, "if we see fit," and they were told that the legal interpretation of these words was that "if you see fit you shall," his reply was that they were not lawyers at that table. They were ordinary Englishmen of common sense, and the ordinary interpretation of the words entailed the exercise of discretion. The Council exercising its discretion acted as it did. The work of the members of the Council had been rudely interfered with, and the question was whether it was of any use for them to continue this work of inspection of examinations. What was the use of inspecting bodies if they had no power of action? It seemed to him that the Act would require to be altered so as to enable the Council to be of any further use, and those words would have to be removed from the Act or interpreted in some intelligible way. They were told that the Privy Council had not intended to interfere, and had not, in fact, interfered with the discretion and usefulness of the Medical Council. That, he maintained, was not the opinion of the majority of those who sat around that table. He thought it would be found that their authority had been most seriously encroached upon and their usefulness greatly impaired, and that, in fact, their action as a statutory body appointed for definite purposes was completely stultified.

The PRESIDENT said it would be the duty of the Medical Council to see that a proper standard of proficiency was required at the examinations and to report to the Privy Council.

Dr. GLOVER said he could not take the view that Sir Dyce Duckworth did. He had this advantage over Sir Dyce Duckworth, that he had heard the proceedings before the Privy Council on both occasions. He was convinced that the Privy Council acted as if they felt the greatest respect for the General Medical Council, and he saw nothing in what had happened to alter that view. He hoped the Council would clearly understand that what had been established was that there had been some error in the Council's proceedings. They did not lose any moral force as the result of the decision. They had the same rights as they ever had, and if any representation required to be made in future as to the inefficiency of one of the qualifying bodies that representation would have effect. In this case, according to the opinion of the Privy Council and according to the General Medical Council's own legal advisers, the Council had proceeded in a wrong manner. He did hope, therefore, that the Council would not adopt Sir Dyce Duckworth's opinion that there was anything disparaging to the General Medical Council in the course which the Privy Council had taken. If the examinations of the Apothecaries' Hall of Dublin did not in the new circumstances proceed to the Council's satisfaction they could make a representation to that effect to the Privy Council. In this instance he was convinced that the Privy Council had acted under a great sense of responsibility, and were only anxious to act with the General Medical Council to promote the ends that Council had in view.

Mr. TICHBORNE, who mentioned that he also had heard the whole proceedings in the appeal, endorsed all that Dr. Glover had said, and he was quite sure that the Privy Council had treated the General Medical Council with the greatest respect. To his mind that was the reason why the authorities of the Apothecaries' Hall had been sent back to the General Medical Council.

Mr. TEALE said he also could not agree with Sir Dyce Duckworth. The whole thing had arisen because the Council had got into an anomalous position. The body the General Medical Council brought before the Privy Council was not the Apothecaries' Hall, but the Conjoint Board, a body which had ceased to exist before the General Medical Council's representation could take effect. The Council had thought they were able to exercise a certain discretion, but the decision of the Privy Council showed that they could not. The decision did not alter his mind in the least. What they had to do was to appoint examiners as the Privy Council directed, and having done that if the examinations were not to the Council's satisfaction they could report to that effect.

Professor GAIRDNER pointed out that when this matter last came back to them from the Privy Council it came back in an indefinite form, and in connexion with the application by the Apothecaries' Hall to appoint, not only surgical, but also medical examiners. That was the last shape in which the matter was last before them, and all the proceedings bore on that aspect. In that aspect of it he agreed with a great deal that Sir Dyce Duckworth had said. The Council had condemned the medical side of the Apothecaries' Hall, and it was apparently a very inconsistent thing for them to help a body to get examinations which it had been conducting inefficiently. What the Privy Council asked them to do now was something quite different in principle. It was not the medical examiners, but the surgical, that they were now asked to appoint, and the reasons for their being directed to appoint these surgical examiners had no reference to the efficiency of the Apothecaries' Hall in its own department. Its reference was simply to the fact that unless the Council appointed these examiners the Apothecaries' Hall would be disabled by a side wind from conducting examinations that would qualify because the Hall could not get any of the other bodies in Ireland or elsewhere to give these examiners. While agreeing with Sir Dyce Duckworth that the position was a difficult one for the Council, he yet thought it amounted only to this, that they had simply to do now what they had statutory powers to do in order to enable the body in question to conduct examinations in legal form legally.

Sir WILLIAM TURNER pointed out that the proposals raised the question whether they should appoint examiners at once or defer the appointment till a committee had considered the matter. The amendment included the question of remuneration. That was a very important matter and one which was specially referred to in the Act. There was a specific sub-section of the Act referring to it, and it seemed to him that they could not pass such a motion as that proposed by Mr. Tichborne in the form in which it was given to them because they must specify the amount of remuneration that was to be given. The amendment, therefore, was a proposal which he thought they might well adopt at this stage of the discussion.

Mr. TICHBORNE was perfectly willing to accept the general principles just laid down. Reference to a committee would be a perfectly good way of dealing with the matter, but the Apothecaries' Hall ought to be represented on any committee appointed. The Hall would be prepared as regards any remuneration the Council might fix. When last the Council granted examiners for the Hall they fixed the remuneration at five guineas for each of the examiners at each examination.

With the consent of the seconder the motion was withdrawn and Mr. Bryant's proposal was unanimously adopted. A committee of the following seven members was then appointed—viz., Mr. Bryant, Mr. Tichborne, Dr. Heron Watson, Mr. Teale, Dr. Batty Tuke, Mr. Brudenell Carter, and Sir John Banks.

On the motion of Dr. THORNE THORNE, seconded by Dr. MACALISTER, it was agreed to print and circulate among the members of the Council the full report of the proceedings in the appeal to the Privy Council.

Midwives Registration Bill.

The next business was the consideration of a communication from the Privy Council transmitting a copy of the Midwives Registration Bill introduced into the House of

Hosted by Google

Commons on Feb. 9th, together with a resolution thereon adopted by the Executive Committee on Feb. 22nd last. The following were the documents :—

(i.) COMMUNICATION FROM THE PRIVY COUNCIL.

"78,360. "Privy Council Office, Whitehall,
"February 16th, 1897.

"SIR,—I am directed by the Lords of the Council to transmit to you, to be laid before the General Medical Council, the accompanying copy of the 'Registration of Midwives' Bill, which has been introduced this session in the House of Commons by Mr. Tatton Egerton and others.

"I am to request you to be so good as to move the General Medical Council to favour their lordships with their opinion on the Bill in question. "I am, Sir, your obedient servant,

"C. L. PEEL.

"The Registrar of the General Medical Council."

(ii.) RESOLUTION BY THE EXECUTIVE COMMITTEE.

"*Resolved*: 'That the following be sent to the Privy Council as the answer of the Committee to this communication :—

"'That, as the meeting of the General Medical Council does not take place until May 24th, the Registration of Midwives Bill cannot be submitted for the opinion of the Council until that date; but that under these circumstances the Executive Committee, who have authority to act for the Medical Council, beg to forward for the information of the Lords of the Council the enclosed resolutions, which were adopted by the Council on Nov. 29th, 1889, and on June 5th, 1895, on the Midwives Registration Bill, transmitted by the Lord President on May 16th, 1895, with the request that the Council would favour him with observations on it.'"

The resolutions referred to in the foregoing were :—

1. Moved by Sir JOHN SIMON, and seconded by Sir WALTER FOSTER, and agreed to :—

"That, if any department of Her Majesty's Government were constituted controlling authority in relation to local arrangements made under statute for the licensing and registration of midwives, the Medical Council would, if the Government department so wished, be willing to advise as to the general rules of education, examination, and discipline which ought to be established in the matter; but the Council would not be able to discharge, and would, therefore, not be prepared to undertake, any duties of detail as to the registration of midwives or as to the local arrangements for licensing and controlling them.—Nov. 29th, 1889."

2. Moved by Sir WILLIAM TURNER, seconded by Mr. TEALE, and agreed to :—

"That it should be pointed out that the General Medical Council, as the supervising authority over the Midwives Board, will require to devote each session a portion of its sittings to the business of that Board, and will incur expenses in connexion therewith. As the funds of the Council consist solely of the fees paid by medical practitioners for admission to the Medical Register, it does not seem to be equitable that they should be expended in payment of work to be imposed by statute on the Council in connexion with the supervision of the Midwives Board. Further, the practitioners in Scotland and Ireland would be contributing to pay the expenses of an Act applying only to England and Wales. The Council would point out that as the Bill has been introduced in the interests of the public, and as the midwives are not in a position to pay large fees for purposes of registration, a grant should be made by the Treasury to meet the expenses of the Midwives Board and the additional charges imposed on the Medical Council.—June 5th, 1895."

On the motion of Sir WILLIAM TURNER these several documents were entered on the minutes.

In answer to Dr. Bruce, Sir WILLIAM TURNER stated that no further communication had been received from the Lord President on the subject.

Mr. BROWN said that the communication of the Executive Committee did not reply to the request for an opinion of the Council on Mr. Tatton Egerton's Bill. They should see that the Privy Council were furnished with an opinion, and he therefore moved that the Bill be referred to a committee to consider and report.

Dr. RENTOUL rose to a point of order. A few days ago, he said, he wrote to the President asking if he might send up amendments to the Midwives Registration Bill. The President had replied that it would be out of order to do so, and that the Council would be out of order in considering the Midwives Registration Bill. He wished to know if the President adhered to that view.

As the President did not rise to reply,

Sir W. TURNER said that Mr. Brown's motion was before the Council. Did Dr. Rentoul second it?

Dr. RENTOUL: I want a ruling.

The PRESIDENT said that the General Medical Council would have nothing to do with the Midwives Bill. They had expressed that opinion more than once, and until the former resolution was rescinded the question could not be re-opened.

Sir WILLIAM TURNER said it was usual at the meetings of the Council to put motions in writing. He had not received Mr. Brown's, and it had not been seconded. Would Mr. Brown put his motion in writing?

Mr. BROWN: Will you speak to the chair, sir? I will take my orders from the chair.

Sir WILLIAM TURNER: I am speaking in my official capacity as Chairman of the Business Committee, and I am merely telling you what is the mode of conducting business.

Mr. BROWN: I should take it much more kindly from the President. You should speak to the chair.

Dr. BRUCE seconded the motion. He thought it was the Council's duty in all courtesy to the Privy Council to take this matter into consideration.

The PRESIDENT: You must first move that the previous resolutions of the Council be rescinded.

Dr. GLOVER did not see that there would be anything improper in referring this Bill to a committee. In 1890 there was a Midwives Registration Bill sent to them for their opinion and it was referred to a committee. He had further to remind the Council that that committee went through another Bill sentence by sentence, and passed a series of resolutions which were embodied in the volume of their proceedings for 1895. If they referred Mr. Tatton Egerton's Bill to a committee very possibly the committee would come to the same conclusions as were come to in 1895, and there would be no harm if they did. If Mr. Brown and Dr. Rentoul could satisfy the Council that there was reason for altering the previous resolutions there would be nothing improper done. He hoped there was nothing inconsistent in taking that course, and he should therefore support the proposal to refer the Bill to a committee.

Dr. MACALISTER said he should be sorry if the motion was carried. He was satisfied with the existing resolution. It touched the only two points with which the Council were concerned. To again spend days and days over the subject would be waste of time. Everybody knew that the Bill in question had no chance of passing during this session or of coming up again. It was dead, and that was an additional reason for not seeking to discuss it in the Council.

Dr. MCVAIL said that as a Crown member appointed by the Privy Council he could not take the view of the matter which Dr. MacAlister took. He wished, however, to point out that the Privy Council's request was made on Feb. 16th, and, as they had now reached May 25th, did the Privy Council still desire that the General Medical Council should consider the Bill and give an opinion of it? They should inform themselves on the point before proceeding further. He moved accordingly.

Dr. THORNE THORNE seconded the motion. He was firmly convinced that it would be an absolute waste of time to consider the Bill in question so far as the present session was concerned; but they must remember this, that when the Privy Council asked their opinion on the previous Bill they had spent two whole days in formulating that opinion, and he thought that that fact afforded ample ground for complying with the present request. Still, if they went to the Privy Council now and asked if they were to consider the matter, he thought they would be told that they need not take it into consideration.

Mr. BRUDENELL CARTER agreed that it would be desirable to get the information Dr. McVail suggested, but in writing for it they should point out that the opinions of the Council on the registration of midwives had been already fully laid before the Privy Council in the minutes for 1895.

After some remarks by Dr. HERON WATSON, Mr. BROWN and Dr. BRUCE consented to withdraw their motion, and Dr. McVail's proposal was agreed to in the following form :—

"That inquiry be made as to whether the Privy Council still desires that the Midwives Registration Bill sent on Feb. 16th should be considered during the present session of the Medical Council."

The Council adjourned.

WEDNESDAY, MAY 26TH.

The Council met again to-day with a full attendance of members.

Resignation of the Registrar.

Mr. ALLEN, acting clerk, read a letter from Mr. W. J. C. Miller, intimating that on account of ill health he desired to resign the office of registrar which he had held for a period of twenty-one years.

Sir WILLIAM TURNER said that this letter was before the Executive Committee at its meeting on Monday, and with a view of facilitating the consideration of the situation they had framed the following report, viz. :—

"(*a*) The executive committee recommend the Council to accept Mr. Miller's resignation as from May 31st.

"(*b*) The committee having been advised by Mr. Muir Mackenzie that

Hosted by Google

the Council is not empowered to grant a pension or supernumerary allowance to any of its officers, but that a gratuity may be awarded on retirement, they recommend the Council to appoint a committee consisting of the two treasurers and of additional members to bring up a report on this subject at the present meeting of the Council. Also that the same committee should report on the steps to be taken as to filling up the vacancy.

"(c) The committee recommend the following members to act together with the treasurers: Mr. Teale, Dr. Heron Watson, Sir Philip Smyly, Sir Wm. Turner."

In moving the adoption of the first recommendation he wished to say that the Council were losing the services of an officer who had been associated with them for upwards of twenty years, and who as long as he was in the full vigour of his health gave his time and his services without grudging to the work of the Council. He thought he might say that all the members held Mr. Miller in the highest respect and regard, and were extremely sorry to think that the state of his health was such that he felt it necessary to resign his appointment. The legal adviser of the Council had assured them that they had no power to confer a pension upon a retired officer, and in the case of Dr. Hawkins the course was adopted which was now suggested—namely, that a gratuity should be given.

Mr. TEALE, in seconding the motion, spoke of Mr. Miller's power as a mathematician and his literary qualities.

Sir JOHN BANKS said he agreed with all that had been said about Mr. Miller, and hoped the Council would be able to treat him with great generosity.

Dr. MACALISTER and Dr. PETTIGREW also spoke appreciatively of Mr. Miller's qualities and services.

Mr. BROWN suggested that the Council might postpone action until the November session, which would in his opinion be the highest compliment they could pay to Mr. Miller.

The recommendation was then adopted by the Council.

Sir WILLIAM TURNER, in moving the second recommendation, said that the President desired that the committee should also report on the range of the duties of the new Registrar and the remuneration to be paid him.

The recommendation thus amended was agreed to, as was also the third recommendation.

On the motion of Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, it was agreed:—

"That in accepting the resignation of the Registrar, Mr. W. J. C. Miller, the Council desire to place on record its high appreciation of his services during his tenure of office for a period of over twenty years, and to express its regret that, owing to failure of health, it is to lose the benefit of his special tact, urbanity, and knowledge."

Penal Removals from the Register.

Dr. HERON WATSON, on behalf of the Executive Committee, presented a modified set of standing orders to regulate the procedure of the Council with reference to penal removals from the Medical Register. These standing orders, he said, would secure continuity and regularity in the proceedings and protect the decisions of the Council. He begged to move their adoption.

Sir DYCE DUCKWORTH, in seconding the motion, said that this would be found a very much improved edition of the standing orders.

Dr. BRUCE said he wished to suggest a small alteration. In one of the standing orders it was ordered that the complaint and the abstract and the documents which accompanied the complaint should be submitted by the General Registrar to the President, who, if the case were considered by him to be outside the jurisdiction of the General Council, might direct the General Registrar to signify the same to the applicant, but who, if the case in his opinion might come within such jurisdiction, should direct the General Registrar to refer the case to the Committee on Penal Cases. He did not think there was any subject with which this Council had to deal in regard to which they should be more careful and deliberate than the subject of penal prosecutions. This was a department of the Council's work in which the direct representatives of the profession were specially interested. They allowed freely enough that the other members of the Council had the highest regard for the honour and dignity of the profession, but the direct representatives coming into contact with the great body of the profession understood what pressure was exerted by such bodies as the Medical Defence Union in order to clear the Register of names that should not be there. He wished particularly to say that he referred to nothing which had taken place in the past. He thought the standing orders, as drawn up by Mr. Muir Mackenzie, were excellent and met their objects thoroughly, although he wished to call attention to this particular point. His desire was that every case which was brought up should be submitted to the Penal Cases Committee as it was proposed to be constituted. He had the highest respect for Sir Richard Quain, but he thought that no individual should be put in a position where he was bound to determine such nice points. He thought every case should, so to speak, go before the grand jury, and that the grand jury in this instance should be the Penal Cases Committee. He therefore proposed that the standing order should read that the complaint, &c., should be submitted to the President, who should direct the General Registrar to refer the case to the Committee on Penal Cases.

Dr. MACALISTER seconded this amendment.

The PRESIDENT said there were cases so absurd and trifling that they should not be sent to the committee.

Dr. RENTOUL said he desired to support the amendment. He thought it essential that the profession should feel the utmost confidence in the Council. Whether rightly or wrongly, he was afraid medical practitioners felt that the Council had somewhat neglected its duties in looking into these matters, and he thought it would be a good thing to have every case referred to the committee. Further than that, he thought the members of the committee should be paid, because unpaid public work was always badly done work.

Mr. BROWN also spoke in support of the amendment.

The amendment was then put to the Council and carried by a large majority, both as an amendment and as a substantive motion.

Dr. BATTY TUKE moved:

"That the Penal Cases Committee consist of five members—three from England, one from Scotland, and one from Ireland; that the committee meet four times a year if necessary; and that the President shall be empowered to summon the committee at other times if he considers that necessity has arisen."

He reminded the Council that cases from Scotland and Ireland were rare.

Dr. BRUCE thought it was not necessary to create a new committee, and suggested that the Executive Committee might take the work in hand with the assistance of the Branch Councils, who would be able to make inquiries locally.

Dr. PETTIGREW shared this view with Dr. Bruce. He thought it would be a good thing if the Scottish Branch Council met oftener.

Mr. BROWN said he should like to see the Branch Council the Penal Committee for its division of the country.

After some further discussion the motion of Dr. Batty Tuke was carried.

It was also agreed, on the motion of Dr. BATTY TUKE:

"That the President be empowered not to summon the Scottish or Irish members of the Committee unless cases forwarded from either of these countries have been presented for consideration.

"That all documents bearing on cases from Scotland or Ireland shall be submitted to their respective representatives on the Penal Cases Committee, who, in consultation with two other members of the Scottish or of the Irish Branch Council, as the case may be, to be appointed annually by the respective Councils, shall send a report to the President of the General Council to be brought before the Penal Cases Committee at the first subsequent meeting.

Some discussion elicited the opinion that the Standing Orders as modified had not been adopted, and two proposals were made—one that each section should be separately considered by the Council, and the other that the whole be gone into in committee. The former proposal was not pressed, and the motion to go into committee was rejected by 16 votes to 11.

Mr. BRUDENELL CARTER, seconded by Sir DYCE DUCKWORTH, thereupon moved that the Standing Orders as amended be adopted.

Dr. MCVAIL proposed an alteration of Article 15, which stood in the programme in the following terms: "In the event of a resolution for adjournment of the further consideration of the charge being carried the Council, on the case coming on again for consideration, may hear the accused practitioner and the complainant (if any), and receive such further evidence as it shall think fit." He moved to leave out the words "and the complainant (if any)," and that the ending of the Article should be, "and to receive such further evidence as the practitioner shall think fit to lay before the Council."

The PRESIDENT said that these were legal technicalities that ought to be discussed only when the Council's legal advisers were present.

Dr. GLOVER agreed with this view.

Mr. BROWN seconded Dr. McVail's proposal.

Hosted by Google

Mr. BRUDENELL CARTER pointed out that the Article was word for word the same as that which they had been acting upon, and it had worked very satisfactorily, especially in the case of young practitioners who had been led into error. He should be sorry to see it altered.

Dr. CAMERON: Does "practitioner" mean convicted practitioner?

The PRESIDENT: Yes.

The proposal was rejected and the motion for the adoption of the Standing Orders was carried by 18 votes to 2.

A Deputy President.

On the return of the Council after the adjournment for tea,

Sir WILLIAM TURNER intimated that at the request of Sir Richard Quain, and subject to the approval of the Council, he had been asked to take the chair for the rest of the business.

The intimation was received with applause and Sir William Turner presided during the remainder of the sitting.

Dental Business.

Mr. BRYANT, as chairman of the Dental Education and Examination Committee, submitted reports on the qualifying examinations of the four dental licensing bodies of the United Kingdom—viz., the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons in Ireland. The committee reported that all these bodies now came up to the approved curriculum. The English and Irish Colleges had deviated somewhat from the original recommendations of the General Medical Council, but these deviations in no way departed from the Council's wishes, since they all tended to make the practical part of the course of study more complete. The committee failed to see the advantages of Scotland having two dental boards, and recommended that the two should unite and form one conjoint board, so that there would be but one dental licensing body in each division of the United Kingdom. The reports embodied modifications of the existing regulations as to the course of study and examinations to be gone through by candidates for licences in dental surgery.

On the motion of Mr. BRYANT, seconded by Mr. BRUDENELL CARTER, the reports were entered on the minutes. On the question whether the Council should go into committee to consider the various recommendations in detail,

Dr. HERON WATSON expressed the opinion that before they went into committee on the admirable reports that had been presented the Council should consult the licensing bodies concerned on the subject, with the view of carrying these bodies with them in the decisions they might come to. The time that would be spent in doing that would very likely ultimately prove a gain. He moved that the reports be sent down to the bodies with an invitation to them to express an opinion on the recommendations in time to have the same laid before the Council previously to decision upon them at the November session.

Dr. BRUCE seconded the motion.

Dr. MCVAIL drew attention to the recommendation that the Scotch bodies should unite. He said they had no power under the Dentists Act to do so.

Mr. BRUDENELL CARTER and Dr. RENTOUL pointed out that Section 38 of that Act empowered them to do so.

The motion was agreed to, and the Council adjourned.

PRESENTATIONS TO MEDICAL MEN.—Presentations have been made by members of the local ambulance classes in recognition of honorary instructions in First Aid as follows: to Mr. J. F. C. Hossack, F.R.C.S. Edin., of Ipswich, of a meerschaum pipe; to Mr. R. E. Brown, L.R.C.P., L.R.C.S. Edin., of Willington, Durham, of a silver-mounted walking-stick; to Mr. W. S. Anderson, M.D. Glasg., M.R.C.S. Eng., of Chapel-en-le-Frith, Derbyshire, of a medical work, and to Mr. V. J. Greenhough, M.B. Cantab., also of Chapel-en-le-Frith, of a telescope; to Mr. P. Phelps, L.R.C.P. Edin., M.R.C.S. Eng., of Loughborough, Leicestershire, of a dressing-case; to Mr. W. F. Boycott, M.B. Edin., of Manchester, of a gold medal and a walking-stick; and to Mr. S. McC. Boyd, F.R.C.S. Irel., of Manchester, of a handsome walking-stick.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At the Examination in May the following candidates passed in the subjects indicated:—

Surgery.—A. Avent, St. George's Hospital; M. I. Baker, St. George's Hospital; S. R. Bhagtani, King's College Hospital; P. H. Collingwood, St. Thomas's Hospital; R. B. Greaves, Sheffield; A. J. Hull (Section I. and II.), Guy's Hospital; J. S. A. Murphy, Leeds; H. R. Rice, London Hospital; and G. Steel, Cambridge.

Medicine.—F. Adams, St. Thomas's Hospital; H. A. Ahrens, King's College Hospital; J. Ash, St. Thomas's Hospital; A. J. Hull (Section I. and II.), Guy's Hospital; R. A. Lewty, Leeds and St. Mary's Hospital; B. S. Mankar, London Hospital; and J. S. A. Murphy, Leeds.

Forensic Medicine.—T. M. Clayton, Durham; A. J. Hull, Guy's Hospital; R. A. Lewty, Leeds and St. Mary's Hospital; H. H. Monckton, King's College Hospital; C. W. Moore, Manchester; and F. M. Simmonds, Edinburgh.

Midwifery.—F. M. Aldred, Liverpool; C. H. Church, McGill; T. M. Clayton, Durham; G. J. D. Davies, Leeds; C. W. Moore, Manchester; H. R. Rice, London Hospital; and F. M. Simmonds, Edinburgh.

The diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery.—Messrs. Avent, Baker, Church, Clayton, Greaves, Hull, Moore, Murphy, Rice, and Simmonds.

UNIVERSITY OF LONDON.—At the M.B. Pass Examination in May the following candidates were successful:—

First Division.—Richard Hamilton Ashwin, Guy's Hospital; Stanley Longhurst Box, St. Bartholomew's Hospital; Harold Merriman Cooper, St. George's Hospital; Arthur Henry Evans, Westminster Hospital; George Frederick Saunders Genge, Westminster Hospital; Cuthbert Henry Jones Lockyer, Charing-cross Hospital; Raghavendra Row, B.Sc., Grant Medical College, Bombay, and University; and Frederick Charles Sprawson, King's College Hospital.

Second Division.—Percy Crompe Barford, St. Bartholomew's Hospital; William Blair Bell, King's College Hospital; Robert Allan Bennett, Mason College and Queen's Hospital, Birmingham; John Francis Bill, St. Bartholomew's Hospital; Malcolm Cameron, London Hospital; John Samuel Chater, St. Bartholomew's Hospital; William Wheelwright Clegg, Yorkshire College and Middlesex Hospital; John Morton Sim Coutts, University College; Edmund Sprague Dukes, Guy's Hospital; Arthur Earnshaw, Guy's Hospital; Edward Fisk, Guy's Hospital; Ella Catherine Flint, London School of Medicine and Royal Free Hospital; Herbert Fox, Middlesex Hospital, Glasgow Infirmary, and University of Aberdeen; Fred Claude Bromley Gittings, Middlesex Hospital; John Crisp Griffiths, B.Sc., Mason College, Queen's Hospital, and General Hospital, Birmingham; Ernest Wm. Hey Groves, B.Sc., St. Bartholomew's Hospital; William Hardcastle, Charing-cross Hospital; Sarah Kaye, London School of Medicine and Royal Free Hospital; Urania Latham, London School of Medicine and Royal Free Hospital; William Liversidge, University College; James Laidlaw Maxwell, St. Bartholomew's Hospital; Julius Moore, Guy's Hospital; Percy Northcote, St. Thomas's Hospital; John Owen, Royal Infirmary, Liverpool; Harold Everett Pace, London Hospital; William Redpath, St. Thomas's Hospital; Francis Montgomery Seal, University College; Stanley Francis Smith, St. Bartholomew's Hospital; Harold Weeks, St. Bartholomew's Hospital; and Stanley Whicher, Guy's Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATIONS.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

H. J. Flanegan, L.R.C.S. Irel., &c.; G. W. Joyce, L.R.C.S. Irel., &c.; and J. R. Wallace, L.R.C.S. Edin., &c.

The following candidates passed the primary part of the examination:—

G. W. Little; J. M'Donald; H. G. Martin, L.R.C.S. Irel., &c.; D. P. O'Brien, L.R.C.S. Irel., &c.; and H. J. C. Wallace.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. S. Mendes da Costa has qualified as *privat-docent* of Dermatology and Diseases of the Urinary System.—*Basle:* Dr. A. Gönner, *privat docent* in Midwifery, has been appointed Extraordinary Professor.—*Berlin:* The title of Professor has been granted to Dr. E. Grawitz, *privat-docent* of Internal Medicine.—*Beyreuth (French Faculty):* Dr. J. la Bonnardière, of Lyons, has been appointed Professor of Therapeutics and Hygiene, in succession to the late Dr. Boyer.—*Bonn:* Dr. Edmund Hummelheim has qualified as *privat-docent* of Ophthalmology.—*Breslau:* Dr. Conrad Alexander, *privat-docent* of Internal Medicine, has been appointed Extraordinary Professor.—*Budapest:* Dr. Thomas von Marschalkó has qualified as *privat-docent* of Dermatology and Syphilography.—*Erlangen:* Dr. Gustav Specht has been appointed Extraordinary Professor of Psychiatry; Dr. Ludwig

Hosted by Google

Heim, *privat-docent* in Würzburg has been appointed Extraordinary Professor of Hygiene and Bacteriology.—*Halle:* Dr. Vahlen has qualified as *privat-docent* of Physiological Chemistry and Pharmacology.—*Kazan:* Dr. Bodbielski has qualified as *privat-docent* of Pathological Anatomy.—*Leipzig:* Dr. M. Siegfried has been appointed Extraordinary Professor of Physiological Chemistry; Dr. Dolega has qualified as *privat-docent* of Internal Medicine.—*Munich:* Dr. Hermann Dürck, Assistant in the Pathological Institute and Prosector in the City Hospital, has qualified as *privat-docent* of Pathological Anatomy.—*Rostock:* Dr. Ricker, formerly Assistant in the Pathological Institutes of the Universities of Zurich and Halle, has qualified as *privat-docent* of Pathological Anatomy and Bacteriology.—*St. Petersburg (Military Medical Academy):* Dr. B. Tarnovski, the well-known syphilologist, is retiring from his professorship after thirty-five years' service.—*Würzburg:* Dr. Wilhelm Reubold, Extraordinary Professor of Forensic Medicine, has retired, being seventy years of age.

THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.—The annual meeting of this hospital was held on May 19th. The Bishop of Stepney, speaking from the chair, emphasised the fact that the lease of the building at present occupied would expire in three years, and he strongly urged upon the committee the need of a new building which, according to the annual report, would cost from £10,000 to £15,000. He hoped that this difficulty would eventually prove to be a stepping-stone to a higher success. At the same time, he felt that it would be almost hopeless to commence such a fund during the present year, in which funds of all kinds and expenditure, unusual both in character and extent, were becoming almost universal. The Prince of Wales's Hospital Fund, excellent in its aims, must, he knew, cause great anxiety to hospital managers in its general effect upon the subscribing public and upon the Hospital Sunday Fund. The Rev. F. K. Povah, Honorary Chaplin to the hospital, said that according to the published figures, when construed in the most liberal manner, the Prince of Wales's Fund did not reach £40,000 a year, the total of an average Hospital Sunday collection. Mr. J. R. Diggle encouraged the committee to face the evident necessity for a new building. Mr. Pearce Gould, honorary surgeon to the hospital, reminded the meeting that it was at this hospital that the first operation for the removal of a tumour of the brain had been performed on the living subject, and asserted that a modern building was a necessity from the point of view of the staff, no less than in the interests of the patients.

ANNUAL MEETING OF THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The twenty-first annual meeting of this association was held on Monday last at the rooms of the Royal Medical and Chirurgical Society, Hanover-square. The newly-elected President, Dr. Sims Woodhead, took the chair. The honorary secretary, Dr. J. J. Ridge, read the annual report, which showed that there had been an addition of 31 members (abstaining practitioners) during the year, and of no less than 217 medical students, making a total of 453 members and 309 student associates. Of the new associates 79 were connected with English schools of medicine, 135 with Scottish, and 3 with Irish. The official organ of the association, the *Medical Pioneer*, had been sent gratuitously to upwards of 2000 medical men for a period of three months. The prize offered to medical students for the best essay on the Influence of Alcohol on Digestion and Nutrition had been awarded to Mr. J. R. Frost, of University College, Bristol. After other business, Dr. Sims Woodhead delivered a presidential address on the Influence of Medical Men on the Temperance Movement. He pointed out that this was exercised long before the modern extension begun by the seven men of Preston. Even Celsus in many passages spoke of the diseases produced by wine and of the advantages of forbidding it. He had found it impossible to include all the work of medical men in promotion of temperance even in modern days in the compass of an address. It was generally recognised not only that alcohol produced many diseases, but that it was a frequent cause of death by aggravating the symptoms of other diseases; it was also known that the excessive use of alcohol greatly increased mortality. It was impossible to discover any definite line of demarkation between the physiological and pathological action of alcohol. He believed that medical men could do even more than legislators to promote the cause of temperance.—Dr. Morton, Dr. Norman Kerr, Dr. Heywood Smith, Dr. Poole, Mr. W. S. Eccles, Mr. W. McAdam Eccles, and Mr. W. F. Hazel took part in the proceedings.

PROPOSED NEW HOSPITAL FOR WESTBURY.—The idea of commemorating the Diamond Jubilee by the erection of a cottage hospital at Westbury, Wiltshire, has been energetically taken up, and last week it was announced that £400 had been promised towards its erection and £70 to the maintenance fund. Mr. W. H Laverton has given a site, £100, a yearly subscription of £20, and 15,000 bricks.

THE PONTYPRIDD BOARD OF GUARDIANS AND POOR-LAW RELIEF.—At the meeting of the Pontypridd board of guardians, held on May 19th, Mr. Bircham, the Local Government Board inspector, attended, and stated that the board had spent in 1896 the sum of £22,000 in relief of the poor and £10,000 in the working of the board, making a total of £32,000. He suggested that in the future no relief should be given to any new applicant without the fullest inquiry.

DEATH OF THE FOUNDER OF THE THIRSK HOSPITAL.—Mrs. Lambert was found dead in bed at Sowerby, Thirsk, last week. She was seventy-six years of age, and founded the Cottage Hospital at Thirsk in memory of her late husband, who was for many years in practice there as a medical man. Mrs. Lambert was a well-known and much-respected lady, and her loss will be felt by a large circle of friends.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held at the vestry-room, Wandsworth, on May 12th. In the absence of the President the chair was taken by Surgeon-Major Mark Robinson.—A paper was read by Mr. T. S. Howell, entitled "The Welfare of the General Practitioner."—Having referred to the fact that this year was the diamond jubilee of his entrance into the profession, Mr. Howell dwelt upon the importance to the practitioner of retaining his proper duties in his own hands and not delegating them to others. Stress was laid upon the advantage to medical men of dispensing their own medicines and upon the evil of allowing the modern race of nurses too free a hand in dealing with patients.—A discussion followed, in which Mr. Richard Oram, Mr. Hugh Ker, Mr. M. G. Biggs, Mr. W. G. Dickinson, and others took part.

AN UNREGISTERED DENTIST FINED.—Before the Stipendiary at the Brighton Borough Bench on May 18th an adjourned summons was heard against one Moss Harris for using the title of "dentist" contrary to the provisions of the Dentists Act, 1878. The hearing of the case had been adjourned pending an application in the High Court for a *mandamus* to compel the General Medical Council to place the names of several gentlemen on the Dentists Register. A *mandamus* was refused. For the defence it was urged that Mr. Harris commenced to practise about twenty-five years ago, some years previously to the passing of the Dentists Act of 1878. Mr. Harris did not apply before Aug. 1st, 1879, to have his name put on the Register, and consequently lost his right to be registered. When he did apply the General Medical Council said in effect: "As far as we can see we should have put you on had you applied in time, but we must draw the line somewhere, we can't be putting people on for ever and ever." It was contended also that there was nothing in the Act to prevent a person practising dentistry, though unregistered, so long as he did not use words implying that he was a dental practitioner or a registered dentist. That merely applied to the theoretical portion of dentistry which was concerned with the management of teeth, and did not apply to the most important branch of defendant's work, the making of teeth. The Stipendiary said there must be a conviction. He did not wish to express any opinion as to whether the word "dentist" was or was not in the shop window as stated in evidence, but there was no doubt that other words amply and strongly calculated to cause anyone to think he did claim for himself the title of dentist and was specially qualified to practise dentistry were used. An attempt had been made to separate the functions of dentistry, but he did not think it was possible to do so. A fine of £5 was imposed, four guineas being also allowed as solicitor's costs, and £1 1s. 6d. as court fees; or in default, twenty-one days' imprisonment with hard labour.

THE ROYAL BERKS HOSPITAL, READING.—At a special meeting of the court of governors of this institution the members of the firm of Messrs. Huntley and Palmer were elected vice-presidents of the hospital in recognition of their recent gift of £7000 for the endowment of beds. This well-known firm have always been most liberal supporters of the hospital, and the compliment which has been conferred upon them is well deserved.

MUNIFICENT GIFT TO ROCHDALE INFIRMARY AND DISPENSARY.—The proposal to celebrate the Queen's reign by increasing the endowment of this institution has been met with a most generous gift from the trustees of the late Mr. James Holden, of High Birch, Marland. A grant of £18,000 has been made to the Infirmary governors, with which to endow the new wing of the building. With the £2000 which was specifically left by Mr. Holden to the Infirmary, the additional grant now made brings the total amount by which the institution benefits up to the sum of £20,000. The total sum now promised to the Endowment Fund is not far short of £23,000.

UNIVERSITY OF DURHAM.—The present and past medical students of the University of Durham entertained Professor Philipson and Professor Arnison at a complimentary dinner last week at Newcastle-upon-Tyne. After dinner a beautiful silver bowl, suitably inscribed, was presented to each of them by one of the most recent graduates, Mr. Patterson, M.B., a distinguished student of the school. Both Dr. Philipson and Dr. Arnison replied to the kind and touching allusions made by Mr. Patterson to their long connexion with the infirmary, and expressed their regret at having to terminate their connexion with the students as clinical teachers.

THE DEVON AND EXETER HOSPITAL.—The annual meeting of this institution was held on May 20th, under the presidency of Mr. A. M. H. Walround. The report stated that during the year 1611 patients had received treatment as against 1621 in 1895-96; the number of out-patients treated during the year was 4212; 817 in-patients were discharged and became out-patients and 161 remained in the hospital on Lady Day, 1897. The average daily number of in-patients was 152 as against 160·3, the average cost of each patient being £5 17s. 9d. and the total cost per bed £40 9s. 7½d. The income for the year was £7306 2s. 7d. and the expenditure £8662 3s. 1d. leaving a deficiency of £1356 0s. 6d. The private nursing staff continued to be more than self-supporting, the earnings for the past year having exceeded those of 1895-96 by £45. The demand for the services of the nurses had even been greater, and abundant testimony of the appreciation of their work had been given.

WHITSUNTIDE HOLIDAY ARRANGEMENTS: WHITSUNTIDE ON THE CONTINENT.—For the convenience of visitors to the Brussels Exhibition cheap tickets available for a week will be issued *viâ* Harwich and Antwerp. The Great Eastern Railway Company's Brussels Service has been accelerated, and passengers leaving London in the evening and the North and Midlands in the afternoon reach Brussels next morning after a comfortable night's rest on board the steamer. For visiting the Hague, Amsterdam, and other parts of Holland, the Rhine, North and South Germany, and Basle for Switzerland, special facilities are offered *viâ* the Company's Harwich, Hook of Holland route, through corridor carriages being run to Amsterdam, Berlin, Cologne, and Basle from the Hook of Holland. The General Steam Navigation Company's fast passenger steamers *Peregrine* and *Seamew* will leave Harwich on June 2nd and 5th for Hamburg, returning on June 6th and 9th.

UNIVERSITY OF CAMBRIDGE.—The proposal to confer the title of B.A. upon women was on May 21st rejected by the unprecedented majority of 1707 to 661 votes. It is hoped that the vexed question will, after this unmistakeable expression of hostile opinion, be allowed to rest. The way is now open for a solution of another kind which will involve no interference with the present constitution of the University. The simplest plan would undoubtedly be the acquisition by Newnham and Girton Colleges of power to confer degrees on duly qualified women. The facilities for instruction and examination now freely afforded by the University might continue unchanged, but the duty of giving an academic title to women would be reserved for the institutions which are best fitted to guide and control them.—The Reade Lecture on Recent Researches in Terrestrial Magnetism will be delivered by Professor A. W. Rücker in the Senate House at noon on Wednesday, June 9th.—A special class in Practical Histology will be held in the Long Vacation by the Master of Downing (Dr. Hill) and Dr. Barclay-Smith, beginning on July 6th.—The General Board of Studies propose to establish a University lectureship in Experimental Psychology, including the Physiology of the Senses. The appointment will probably be made before the end of the present term. Dr. Rivers, of St. John's College, is already conducting two highly successful classes in the subject at the Physiological Laboratory, and will probably be appointed to the lectureship.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The London Water Question.

THE Government, in fulfilment of its promise to do something this session to strengthen the position of the ratepayers in London with reference to the Water Companies, has introduced a Bill enabling individual ratepayers and local authorities to take complaints with reference to the water-supply before the Railway and Canal Commissioners. It is not intended that this power shall interfere in any way with the existing power of making complaint to a magistrate or the Local Government Board.

Infant Life Protection Bill.

The following clause has been added to the Infant Life Protection Bill, namely:—"Any person retaining or receiving an infant under the age of two years on consideration of a sum of money not exceeding £20 paid down, and without any agreement for further payment, as value for the care and bringing up of the said infant until it is reclaimed or of an age to provide for itself, shall within forty-eight hours from the time of receiving such infant give notice of the fact to the local authority. If he does not give the notice required by this section, he shall be liable to forfeit the amount of any sum received by him in respect of such infant, or such less sum as the Court having cognizance of the case shall deem just, and the Court shall give directions as to the manner in which the sum forfeited shall be applied for the benefit of the infant, and shall, if necessary, cause the infant to be removed to a workhouse or place of safety, and the master of such workhouse shall receive such infant, which shall be maintained in the workhouse or place of safety until it can be otherwise lawfully disposed of."

Compensation for Injury to Health.

Before entering upon the Committee stage of the Workmen (Compensation for Accidents) Bill the House of Commons on Monday, May 24th, engaged in an interesting debate on the point whether the Bill should be extended so as to give compensation to workmen for injuries to health arising out of, and in the course of, their employment. Mr. Tennant, who proposed that it should be so extended, gave some account of the excessive mortality among file makers and of the frequent cases of lead-poisoning. He told how, in the case of the Newcastle Infirmary alone during the seven years since 1890 no fewer than 228 cases of lead-poisoning were admitted, of which 107 ended in death. A girl, aged seventeen years, employed for three years in the lead process, had to go to hospital for lead-poisoning, and left almost totally blind. Another girl, of the same age and in the same employment, was attacked with partial paralysis, and after twelve months in hospital was discharged, but with the loss of her sight. Representations had been made to her employers, but nothing had been done for her. Another girl, aged eighteen years, who had been employed in the lead process since January, 1896, was seized with a fit in the January of this year, and had now been discharged from hospital with the loss of sight in one eye and with her general health so impaired that she could not hope ever to be able to work again. The Government, while expressing sympathy with the proposed extension of the Bill, said it would greatly complicate the measure and make it extremely difficult to pass, and on these grounds resisted it. On a division the proposal was rejected by 233 to 144 votes.

HOUSE OF COMMONS.

THURSDAY, MAY 20TH.

Medical Examination of Letter Sorters.

Mr. Lough asked the Secretary to the Treasury, as representing the Postmaster-General, whether, whereas under the Tweedmouth Report only two medical examinations were required for men on probation for appointment to sortherships, many who had already passed two examinations were now required to pass a third; and whether, if this were so, the Postmaster-General would see his way to remove this obligation in the case of existing probationers.—Mr. Hanbury replied that the

Hosted by Google

Tweedmouth Committee recommended that the probationary period of two years with three medical examinations should be reduced to one year with two medical examinations, one at the beginning and the other at the end of the period. Under the old system the intermediate examination was not quite so stringent as the other two, and the Postmaster-General feared that it would not be possible to regard it as satisfying the requirements which the Tweedmouth Committee had in view. All concerned would therefore still have to undergo the final examination which was necessary before the appointments could be confirmed, but the probationers who had not passed the intermediate examination would, of course, be relieved from the obligation of undergoing it.

FRIDAY, MAY 21ST.

Death in a Workhouse.

Mr. Crilly asked the President of the Local Government Board if he could now inform the House as to the result of his inquiries respecting the death of the old woman, Margaret Ross, upon whose body an inquest was held in the Hackney Coroner's Court on May 3rd, when it appeared in evidence that the deceased had been an inmate of a City union workhouse, that her age was seventy-seven years, and that she had been found dead on the previous Thursday beside the washing pail which she had been using in her work, and that the workhouse authorities had been in the habit of compelling this old woman to clean out a large ward containing twelve beds.—Mr. Chaplin replied that he had been in communication with the guardians of the City of London on this subject, and he had also obtained copies of the depositions taken at the inquest in the case. It appeared from the medical evidence and a post-mortem examination that the death of the poor woman was instantaneous—from natural causes, and due neither to syncope nor weakness. It was not the case that the workhouse authorities compelled her to clean out a ward. She had, up to some nine days before her death, been employed in the needle-room, and it was at her own special request that she was allowed to undertake the duty of keeping a dormitory clean, as she preferred this to the more sedentary work, and she was quite capable of undertaking it.

The Form of Oath Administration.

Sir Walter Foster asked the Attorney-General if his attention had been called to the growing fear of infection attaching to the ordinary form of English oath as administered in courts of justice, and whether it was the intention of the Government to introduce a Bill to alter the ordinary form of English oath, and to abolish the objectionable practice known as kissing the book in the administration of oaths of all descriptions.—The Attorney-General (Sir Richard Webster) said that his attention had been called to the question of the desirability of changing the form of oath. He thought the fear of infection had been somewhat exaggerated. Under the provisions of the Oaths Act of 1888 witnesses were now permitted to take the oath in the Scotch form in which it was unnecessary to kiss the book. He would, however, consider whether any further amendment of the law was required.

Workhouse Administration in Ireland.

In the course of a debate on the vote for the expenses of the Local Government Board in Ireland Mr. Gerald Balfour, Chief Secretary, said he was not satisfied with the workhouse system in Ireland, and he had brought in a Bill thoroughly to reform it. Unfortunately, however, it would not be possible to pass it during the present session. At the same time he hoped sooner or later to see an amalgamation of unions, which would be likely to form the best foundation for workhouse reform in other directions. He had included in his Bill the adoption of the system of boarding out pauper children.

MONDAY, MAY 24TH.

Lead Poisoning.

Mr. M'Kenna asked the Secretary of State for the Home Department whether his attention had been called to the case of James A. Garvey, aged seventeen, a lead filer, lately employed at the Electrical Power Storage Company's works, Millwall, who died recently from the effects of lead poisoning; whether he was aware that there was only one bath at the works at which from forty to fifty boys were employed, and that the regulation compelling the use of the bath was habitually disregarded; and whether he proposed to take any steps under the circumstances.—Sir Matthew White Ridley replied that his attention had been called to this case, but he was unable to find on inquiry that there had been any breach of the Factory Acts or the special rules which had been made for electric accumulator works. Employers were required by those rules to provide a bath; this was done at the works in question and a time for bathing appointed for each person employed. It was not obligatory at present, however, on the workers to use the bath, and he regretted to find that at these works bathing had often been omitted. It might become necessary to take steps to remedy this.

Death Certification.

Mr. Macdona asked the Secretary of State for the Home Deparment whether his attention had been drawn to the statement made by the London Association for the Prevention of Premature Burial in THE LANCET of April 24th [1], that in England and Wales 16,000 persons were annually buried without medical certificates of any sort; and whether the Government would take the matter into its serious consideration so as to prevent as much as possible persons being prematurely buried. Sir Matthew White Ridley said he had not seen the statement to which the honourable member alluded, but it was not the case that 16,000 persons were buried annually without medical certificates. The number of uncertified deaths in 1896 was 11,464, and there had been a steady decrease for many years past, both in the actual number of such deaths and in the proportion which they bore to the total number of deaths. No cases of premature burial had been brought to his notice, nor was he aware that it was a matter which fell within his jurisdiction, but in any case he was unable to see that the obtaining a certificate of death would be a guarantee against a premature burial taking place.—Mr. Macdona asked the right hon. gentleman whether he was not aware that a number of medical men were of opinion that a great number of people were buried prematurely.—Sir Matthew White Ridley said in reply to this that the certificates were given by members of the medical profession. Therefore it followed that in their opinion the persons in regard to whom the certificates were given were dead.

Treatment of Weak and Sick Prisoners in Scotland.

Mr. Hedderwick asked the Lord Advocate whether, under the present prison system of Scotland, imbecile or weak-minded prisoners were associated in cells with other criminals without the personal supervision either of officers or hired attendants, whose duty it should be to see that such prisoners were not maltreated; whether sick prisoners were left to the care of fellow-criminals who were wholly without experience in the treatment of invalids; whether evidence showing that these practices prevailed was given in November last by a number of medical men holding appointments in connexion with prisons in Scotland; and whether, in view of the fact that such practices had been condemned by Commissioners of Prisons and abolished both in England and Ireland, he would undertake at an early date to endeavour to assimilate the prison system of Scotland in these particulars to the more humane modes of treatment obtaining in England and Ireland.—The Lord Advocate said he was informed by the Prison Commissioners for Scotland that when weak minded prisoners were associated on medical grounds they were under the close inspection of prison officers who were responsible that no prisoner was maltreated, but that all were properly cared for, and by the rules the medical officer had to satisfy himself that the arrangements were effective; the sick prisoners were not left to the care of fellow-criminals, and that no record could be found of any evidence given by prison medical officers in November last regarding the care of the sick. The Prison Commissioners were satisfied that the treatment of the sick prisoners was humane, and they had always directed their special attention to this part of prison administration.

Irish Schools and Epidemics.

Mr. Carew asked the Chief Secretary to the Lord-Lieutenant of Ireland whether he was aware that in Ireland the sanitary authority had no power to have schools closed for the protection of public health in the case of epidemics breaking out, while in England the sanitary authority had such power conferred upon it, and would the Government extend the same salutary protective power to Ireland.—Mr. Gerald Balfour said, in reply, that the facts were correctly stated in the first part of the question, though in England the managers of a school might appeal to the Education Department if they considered the notice requiring the school to be closed unreasonable. He should not like to answer the second part of the question without having an opportunity of consulting the Commissioners of National Education and taking their views.

TUESDAY, MAY 25TH.

The Vaccination Question.

Sir William Priestley asked the President of the Local Government Board whether he was able to say what course he proposed to take in consequence of the recommendation of the Royal Commission on Vaccination as to the lymph-supply to be issued in future by the National Vaccine Establishment.—Mr. T. W. Russell made the following reply on behalf of Mr. Chaplin: Shortly after the issue of the Report of the Royal Commission on Vaccination, I issued fresh instructions to public vaccinators by which they are enabled, whenever they deem it desirable, to use calf lymph instead of humanised lymph. I have also been making inquiries abroad as to the preparation and employment of glycerinated calf lymph. The report on this subject has been delayed by reason of the fact that in some Continental countries public vaccination is practically suspended during the winter months, and is only resumed in May. But from the information already before me it is more than probable, in my opinion, that glycerinated calf lymph will be found to present distinct advantages over other forms of vaccine lymph, and one of the points which I shall have to consider will be how far it may be practicable for me to issue a gratuitous supply of vaccine lymph in this form to all registered medical practitioners applying for it. I shall also have to consider how far any considerable change, such as is indicated, in the form or the extent of the lymph-supply from the National Vaccine Establishment will be practicable pending fresh legislation on the whole question.

[1] Our words were: "It is computed that in England 15,000 persons are annually interred without medical evidence of any sort"—ED. L.

Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (5th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY (2nd).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. A. Routh and others. Paper: Dr. A. Routh: Parturition during Paraplegia.

THURSDAY (3rd).—NEUROLOGICAL SOCIETY OF LONDON (Physiological Laboratory, University College, Gower-street, W.C.).—8.30 P.M. Prof. Schäfer: Is there a Direct Relationship between the Motor Paralysis Produced by Lesions of the Cortex and Loss of Sensibility, Muscular or Other? (with experiments). Communication:—Prof. Boyce and Dr. Warrington: Some of the Ascending and Descending Nerve Tracts in the Fowl.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (31st).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Leprosy.

LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. G. Stoker: Chronic Glandular Disease of the Nose and Naso-Pharynx.

TUESDAY (1st).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.).—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Black-friars, 4.30 P.M., Dr. Payne: Prurigo and Pruritus.

ROYAL INSTITUTION.—3 P.M. Dr. E. H. Starling: The Heart and its Work.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Gowers: Clinical Demonstration.

WEDNESDAY (2nd).—LONDON SCHOOL OF MEDICINE FOR WOMEN (30, Handel-street, Brunswick-square, W.C.).—6 P.M. Dr. P. Manson: Animal Parasites.

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Sanitary Appliances.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Schorstein: Bronchiectasis.

THURSDAY (3rd).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Quantitative Estimation of Sugar present in Urine.—Erlich's Diazo-reaction, &c.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. W. Cheyne: Clinical Lecture.

FRIDAY (4th).—ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (Hyde-park-corner, S.W.)—5 P.M. Dr. P. Manson: Diseases of Tropical Climates.

EAST LONDON HOSPITAL FOR CHILDREN (Shadwell).—3 P.M. Dr. J. A. Hayward: Marasmus.

LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Actinomycosis and Glanders.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Tooth: Paraplegia.

ROYAL INSTITUTION.—9 P.M. Mr. W. H. Preece: Signalling through Space without Wires.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

HARTMANN'S HYGIENIC TOWELETTES FOR LADIES.

WE have received samples of a new pattern of Hartmann's towelettes which can now be supplied at a lower price than is charged for the style ordinarily in use. Both kinds, whether the low-priced or the more expensive, are made of Hartmann's patent wood-wool wadding enclosed in gauze, the only difference being in the size of the article. Wood-wool is an exceedingly soft and absorbent substance, which the manufacturers have rendered very suitable for the present purpose by means of a process of treatment which prevents it from cohering into an unserviceable mass when wetted. It has also been used as a material for surgical dressings. The towelettes are about nine inches long, two inches and three-quarters wide, and half an inch thick. The gauze with which they are covered is formed into loops at each end for the convenience of fastening. The towelettes are burned after being used. They are sold in packets of twelve for sixpence, so that the price of each is a halfpenny. The manufacturers are the Sanitary Wood-Wool Company, Limited, 26, Thavies-inn, Holborn-circus, E.C.

CHATTERIS URBAN DISTRICT COUNCIL.

The medical officer of health of this council has made remarks concerning the notification of infectious cases in his district which have caused some surprise at a recent meeting of the Council. One passage in his statement, as it appears in a local paper, strikes us as being particularly unhappy. He publishes an assumption that his private practice is twice the size of the practice of one of his neighbours, and states that in spite of that fact the notifications from his neighbour were doubly as frequent as those arising out of his own experience. The inferences that could be drawn from such a statement are clearly of an uncomplimentary character to a professional rival. The assertions of the medical officer of health have been categorically denied by his brother practitioner, but the neighbourhood will certainly desire to know who is right and who is wrong.

AN INSTRUCTIVE CORRESPONDENCE.

OUR attention has been drawn to a correspondence which has taken place between Mr. H. C. Burdett and the Hon. Stephen Coleridge. Mr. Burdett took the same exception that we ourselves did to Mr. Coleridge's letter addressed to the Prince of Wales, and appearing in the *Times* in March last. Mr. Burdett pronounced it ridiculous nonsense for Mr. Coleridge to write to the *Times* and "describe laboratories attached to hospitals where 'hapless dumb animals daily and hourly are slowly cut up alive without even the pretence of anæsthetics,'" and asked to be supplied with the names of the laboratories referred to. Mr. Coleridge did not supply the names; no one yet has been able to extract their names from him, but he wrote some long letters in which, if he meant anything, he meant to evade the point. Mr. Burdett, however, was obstinate and insisted that it was incumbent upon Mr. Coleridge's honour either to supply the names of the laboratories where "hapless dumb animals are daily and hourly cut up alive without even the pretence of anæsthetics" or to withdraw his statement. Mr. Coleridge continued to refrain from imparting the necessary information, but appeared to think that Mr. Burdett ought to be very much obliged to him for furnishing him "with facts relating to the financial connexion between hospitals and laboratories which your thirty years of hospital study had apparently overlooked." Mr. Burdett repeated his question, which Mr. Coleridge again omitted to answer, preferring to furnish illustrations and inferences instead of facts. It was then pointed out to him that analogy is not usually accepted as proof. Mr. Coleridge replied that his analogies had been introduced "not as proofs of facts, but as aids for the formation in Mr. Burdett's mind of a due estimate of the weight of my inferences." Mr. Burdett summed up the correspondence in the *Hospital* of May 15th by stating that "all the talk about cutting animals up alive without even the pretence of anæsthetics must be looked upon as sheer nonsense." And that is exactly how all sensible people have come to regard Mr. Stephen Coleridge's vapourings. If he had any facts we are bound to suppose that he would communicate them. But he has none. He has been guessing and gassing, and has not the grace to turn off the tap when his neighbours object to the smell. We recommend to the consideration of Mr. Coleridge the speeches of the Prince of Wales and of Dr. Pye-Smith, delivered on Wednesday last at Guy's Hospital.

H. M.—To the best of our belief no such course of instruction is given either at Aix-les-Bains or at an English spa. Our correspondent's best plan would be to get an introduction to one of the medical men who are known to be authorities upon the subject and ask for his advice.

AN OBSTINATE CASE OF ECZEMA: SUGGESTIONS WANTED.

To the Editors of THE LANCET.

SIRS,—About five months ago I was consulted by a patient who has been suffering from chronic eczema on his right leg for seven years. During this time he consulted several medical men in different parts of the country, and used their prescriptions without benefit. I put him on a course of iodides and prescribed him many ointments, stimulating and soothing, such as ointment of tar, ointment of zinc, ointment of sulphur, &c., and at first he improved rapidly; but since then the disease has remained stationary. May I ask you to kindly insert this in THE LANCET in the hope that some brother practitioner will give me the benefit of his experience in the treatment of obstinate cases of eczema. I am, Sirs, yours faithfully,

Addlestone, May 13th, 1897. A. ALAMUDDIN, M.D.

Jolly-Boat-Boy has not communicated his name and address. We are therefore unable to return to him his inclosure. We do not recommend practitioners or give medical advice. Surely in all Paris our correspondent can find a medical man who will treat him on reasonable and proper terms.

THE HEALTH OF THE ARMY IN INDIA.

OUR attention has been called by a correspondent to a communication in the *Pioneer Mail* of April 29th on the above subject, in which great stress is laid on the fact that, although there has been an unquestioned increase of venereal disease in most stations in all the several commands in India, there has, nevertheless, been a striking decrease in the admission-rates of some of them. Some useful information may probably be obtained by local inquiry as to the causes of this difference, but it does not seem to us really to affect the question. The broad fact remains—viz., that the amount of these diseases has greatly increased, and is still apparently increasing, and the quality of the constitutional form of it has become much worse. It does not follow that we need return to the Acts exactly as they were in the past, but it does follow, as it seems to us, that remedial measures of some sort are most urgently required. The Indian Government is now considering what these should be.

COLLES'S FRACTURE AND THE ROENTGEN RAYS.

DR. EUGENE R. CORSON contributes an original article entitled "Some Observations on Colles's Fracture by the aid of the X Rays" to the *New York Medical Record* of May 8th, which tends to correct some notions of this troublesome and unsatisfactory injury and to suggest simple lines of treatment. He gives four figures purporting, respectively, to represent the following cases. 1. Comminuted Colles's fracture, with the styloid process of the radius broken off and tilted out, the callus being rapidly absorbed; the styloid process of the ulna broken off; and displacement of the hand and ulna. 2. Transverse fracture of the left radius one inch above the articular surface, with perfect reposition of fragments; the styloid process of the ulna broken off; and displacement of the hand and ulna. 3. Displacement of the hand and ulna (diagnosed as Colles's fracture, but only a severe sprain with displacement of the hand to the radial side due to rupture of the internal lateral ligament). 4. Displacement of the hand and ulna with the radius intact; the fractured styloid process of the ulna being the only injury to the bones. Dr. Corson finds in his observations proof of the views of Hamilton attaching importance to the rupture of ligaments, especially the internal lateral ligament, aided by rupture of the anterior and posterior ligaments, as the chief cause of the most prominent and unsightly deformity in Colles's fracture, the hand slipping toward the radial side and the ulna forwards and towards the radius. There may be considerable deformity without any fracture, and if there be only transverse fracture of the radius without tearing of the ligaments there may be little displacement and a good result with any treatment. Another of his conclusions is that, as Nelaton taught, the styloid process of the ulna is frequently broken off. The fractures are, he thinks, easily reduced by gentle and continuous extension and a certain amount of flexion, abduction, or adduction, according to the case. The more important part of the treatment is to reduce the inflammation and swelling with fomentations, to keep the forearm and hand perfectly prone and in a direct line with each other on a straight splint, slightly padded to suit the flexures of the forearm, wrist, and palm, extending from one inch below the elbow to the metacarpo-phalangeal joints, so as to admit free movement of the fingers—"a very important matter," as he well says, which tends to prevent that permanent stiffness of the wrist and hand which, more than the deformity, disappoints the patient and the surgeon.

X. Y. Z.—Poverty may be considered an emergency for the purposes of our reply. If circumstances permit of the assistance it is well to have it, but for this reason or that it has often to be dispensed with.

STARVATION PRICES.

To the Editors of THE LANCET.

SIRS,—Copies of the enclosed handbill have been distributed broadcast in this locality I am, Sirs, yours truly,

May 15th, 1897. DISGUSTED.

[ENCLOSURE.]

THE LAMBETH DISPENSARY,

39, LAMBETH WALK.

Established with a view of affording Medical and Surgical advice at the Lowest Possible Fees, and thus obviating the necessity of applying to Charitable Institutions, or being treated by quacks, chemists, &c.

HOURS OF ATTENDANCE.

MORNINGS from 10 to 1. EVENINGS from 7 to 9.
SUNDAYS from 12 to 1 only.

A Physician and Surgeon resides on the premises, and will attend urgent cases at any hour.

SCALE OF FEES.

Advice with Medicine ... 4*d*. Visits with Medicine ... ... 6*d*.
Certificates ... ... 6*d*. Vaccination ... ... 6*d*.
Teeth Extracted ... ... 6*d*.

Patients attending the Dispensary may pay 1*s*. per week for all medicine required, or can be visited at their homes and supplied with medicine for 2*s*. per week. Clubs will be attended at the rate of 2*s*. per member per annum.

The Medical Staff are practitioners of many years' experience in Hospital and private practice.

All requests for Visits must be left at the Surgery before one o'clock, otherwise 1*s*. will be charged for Visit and Medicine.

*** It is regrettable that such prices should be voluntarily accepted by medical men.—ED. L.

Mr. Frank E. Wrench (Maple Creek).—Undoubtedly the world has grown more liberal of late, but if anything is more calculated to retard the well-being of the race than undue distrust it is unjustifiable credulity.

THE PROFESSIONAL VAGRANT.

SOME very pointed remarks were made by an emissary of the Local Government Board—Mr. Davy, one of the inspectors—at a meeting of a Sussex board of guardians the other day. Mention has been made in THE LANCET of a scheme adopted in West Sussex for weeding out the professional vagrant. Bread is supplied in every place on application to the local constable, and a pass-card is handed to the tramp which shows where he has called. At the same time the fact is advertised far and wide that there is no excuse for men to beg for either food or lodging, and *bond-fide* workmen, indeed, are helped on. During the last half-year this had the remarkable effect of thinning out the tramps by over one-third—that is to say, that number less passed through the unions. Every union but one supported this scheme, which cost but the modest sum of £13 10s. in the six months. That union is Horsham. Last week Mr. Davy said that no amount of Local Government Board orders could have produced the unanimity which the remaining unions had themselves secured, and he did not like to see one standing out. It is probable that the Horsham guardians will come into line, and the action of Mr. Davy is the more appreciated from the fact that hitherto the support the Local Government Board has accorded the scheme has been of a partial and almost unofficial character.

Mr. Edward Long.—We do not see how any development of x ray therapeutics could lead to the fortunate results suggested by our correspondent.

"THE PUBLIC HEALTH EXAMINATION AT CAMBRIDGE."

To the Editors of THE LANCET.

SIRS,—What your correspondent "M.D." has to say about the inefficiency of the apparatus in the practical bacteriology applies much more forcibly to the apparatus provided us in the gas and water analyses. The test solutions were not all of the strength ordinarily used in laboratories. The water bath supplied me was so small that it would only accommodate one evaporating dish at a time. I had only one graduated hand-burette, which had to be used for all purposes. The first stand-burette I had given me was broken off about a third of its length and the next given me had so large a diameter, and the spaces denoting tenths of a cubic centimetre were so small, that it was only with the greatest care that small additions of the standard ammon. chloride solution could be made. The two-foot tube supplied to me (after waiting a quarter of an hour for it) was closed at *both* ends and could only be filled by holding it horizontally and dribbling the water through a tiny hole in the side. Seeing this would take twenty minutes to fill I abandoned its use altogether. Time is valuable when only three hours are allowed for a complete analysis of water and a quantitative analysis of three gases. Half an hour at least must be devoted to properly writing out your report, and another half hour is wasted in remedying deficiencies of apparatus or waiting for apparatus and reagents not on your bench to be brought you when another candidate has finished with them. At least four hours should, in my opinion, be given for the practical chemistry, and even then it would be a busier time than the four hours each that are given for practical bacteriology and the practical microscopy. My experience justifies me in complaining that candidates at Cambridge D.P H. examinations are not allowed full opportunity of doing justice to their practical knowledge, but are hampered and confused either by lack of the usual reagents and apparatus or their improper condition. I am, Sirs, yours faithfully,

May 19th, 1897. W. T.

Clerk has done well, although the appearances were suspicious.

A SAPIENT TOWN COUNCIL.

THE medical officer of health of Kidwelly, South Wales, has had some remarkable experiences in connexion with his salary. At first it was fixed at £20 per annum; this was increased to £35, where it stopped for three years, when it was reduced to £12 10s. A year later it went down to £10, but the town saved nothing by this, as when the salary was £20 and over the Local Government Board paid half, but immediately it was under that amount Kidwelly had to pay it all. For this reason the council on May 11th suggested £20 again, but the proposal was lost by eight votes to seven.

THE INTERNATIONAL TROOPS IN CRETE.

CRETE is far from being a desirable station at the present time. Its towns and villages are not the most sanitary and cleanly places in the world. The troops that have been landed in the island are stated to be enjoying excellent health, but there have been two mild cases of small-pox in the Highlanders. Small-pox is rather prevalent among the Cretan population at present. The British and Italian troops, the correspondent of the *Broad Arrow* reports, fraternise a good deal together. The Turkish troops, he adds, are not well clad or equipped, but they are patient, well behaved, amenable to discipline, and good soldiers.

A FLOATING AMBULANCE AT THE SEAT OF WAR.

FROM Volo an Italian correspondent writes that on the 7th inst. he left that port at midday on board the *Albania*, a real "floating hospital," whose *personnel* included Mr. Osborn, with a number of ladies of the English Red Cross, Dr. Müller (a Swiss), and Dr. Cantas (a Greek), assisted by ladies of the Greek Red Cross. They were tending and treating a hundred wounded Greeks and volunteers, while a priest was at hand to vouchsafe the consolations of religion. Besides the cabins, the deck and "bridge" were set apart for the patients lying on stretchers. The weather he describes as "incantevole" (enchanting), in strange contrast to the "tristezza" (sadness) of the floating ambulance, whence the air was filled with the moans of the sufferers. By 5 P.M. two of these had breathed their last. Very severe was the agony of a soldier whose right leg was smashed by a "mitrailleuse." The surgeons attempted amputation, which was performed as the patient lay extended on a table on the "bridge"; but he succumbed under chloroform, so low had the powers of life run. His last words before being fully anæsthetised, uttered with a voice of anguish, were "Emanula, Emanula, piccola madre mia" (Emanula, Emanula, my little mother). By 5 30 P.M. Stylidas was reached and six more wounded, all from Pharsala, were taken on board. These were members of the foreign legion—four English and two Italians. The latter were one Alessandrini of Modena, whose right leg had been traversed by a projectile without its having touched the bone, and one Balducci of Bologna, whose right arm had been similarly perforated by a ball, the bone again remaining intact. There were thirty-three Italians in the foreign legion posted at the extreme left of the Greek lines at Triscoli, a point some ten miles from Pharsala. There, with 700 Greek infantry, the legion, without ordnance, had to face a strong Turkish force with eight cannon. Nevertheless, they pressed on till they came within three miles and a half of Pharsala, by which time the legion had twenty wounded. Nearer Pharsala they came within close range of 7000 Turks. In the encounter Alessandrini and Balducci received their wounds, and Captain Barattazzi (Greek), who commanded the legion, was himself severely wounded. By general testimony the English members of the legion and the Italians fought most courageously of all. In the Greek camp, according to the same correspondent, the medical department was very badly supported and provided. "At Pharsala itself," he adds, "not a single Red Cross ambulance was present." On the voyage of the *Albania* the two dead, accompanied by the priest, were buried at Stylidas, and the same night two more died and were landed for interment next morning at Malcis. By this time the moribund amounted to twenty, mostly with abdominal wounds. One, from a wound on the cranium, had a great part of the cerebrum carried away, but was still active and able to express his wants; another had the hip-joint smashed by a "mitrailleuse." The surgeons say that in this campaign whenever a projectile has touched a bone it has caused a comminuted fracture. One unfortunate among the wounded went raving mad and could with difficulty be kept bound to his stretcher. The wounded officers on board the *Albania* were unanimous in declaring that on the Greek side the fortunes of the campaign were compromised by the paramount blunders of the two retreats, but that the defence can be maintained along the line of the old frontier. They expressed the greatest confidence in Smolenski, who, they said, deserved to be put in supreme command.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Coleshill Chronicle, Rochester Journal, Sheffield Independent, Eastern Morning News, Birmingham Gazette, Newcastle Chronicle, Bradford Observer, South Wales News, Times of India, East Anglian Weekly Times, Pioneer Mail, Rugby Advertiser, Builder, Darwin Post, Preston Herald, Liverpool Daily Post, Kendal Mercury, Leicester Post, Walsall Advertiser, Architect, Alresford Herald, Harrow Press, Southport Visitor, Yorkshire Post, Brighton Gazette, Hastings News, Northampton Mercury, Derbyshire Courier, Dudley Herald, Worcester Advertiser, Weekly Echo (Sunderland), Chatham News, Windsor Chronicle, Maidstone Journal, Sussex Daily News, Huddersfield Examiner, Lancashire Express, Wellington News, Bristol Mercury, Kent County Examiner, Folkestone Chronicle, Kidderminster Shuttle, Portsmouth Times, Yarrow Express, Scotsman, Leeds Mercury, Hampshire Independent, Bromley Herald, Local Government Chronicle, Hertfordshire Mercury, Mining Journal, Weekly Free Press and Aberdeen Herald, City Press, Reading Mercury, Sanitary Record, Maidstone and Kentish Journal, South Africa, Surrey Advertiser, Reynolds' Newspaper, Nuneaton Observer, Local Government Journal, Leek Times, Public Health, Engineer, Isle of Man and Daily Times, Kenilworth Advertiser, West Middlesex Herald, Halifax Courier, Montrose Standard, &c., &c.*

THE RELATIVE VALUE OF IRON PREPARATIONS.

In a paper read before the West Kent Medico-Chirurgical Society the author gives the following results of sixty-five clinical trials conducted by him at the National Hospital for Diseases of the Heart, Soho-square, London, W.

"In every case the hæmoglobin in the blood was estimated; the treatment was then continued for twenty days and the hæmoglobin again estimated. Ten patients were given 10 grains of ordinary coated Blaud's pill from the hospital dispensary three times a day. These pills had probably been made three months or so previously. The average daily increase of hæmoglobin was one-eighth per cent. Ten patients were given 10 grains of freshly made Blaud's pill. The daily increase of hæmoglobin was nearly one-half per cent. Separate sets of five patients were given respectively equivalent doses three times a day of various iron preparations, the average daily increase of hæmoglobin ranging from below one-eighth to one-half per cent. Ten patients were given three times a day eight grains of sugar-coated 'Tabloids' of Blaud pill made by Burroughs, Wellcome & Co. The increase of hæmoglobin was 1·2 per cent. per day." In a later portion of his paper the author explains this great superiority of Blaud pill "Tabloids" as follows:—

"When a 'Tabloid' is swallowed, reaction between the salts takes place on coming into contact with any fluid which may be present in the stomach, and the nascent ferrous carbonate is formed in the viscus itself. Such 'Tabloids' made by Burroughs, Wellcome & Co. are further protected by a coating of sugar. If a 'Tabloid' is cut open, the cream-coloured contents will be seen instantly to change to the dark green ferrous carbonate on the addition of a drop of moisture.

It will thus be seen that the whole weight of evidence from these clinical investigations demonstrates the immense superiority of Blaud pill "Tabloids" over other iron preparations. Fuller details of this series of clinics and samples of Blaud pill "Tabloids" will be forwarded on application.

LIST OF BLAUD PILL "TABLOIDS."

Blaud Pill ... ... 4 gr.
Blaud Pill, 4 gr., with Arsenious Acid, 1-64 gr.
Blaud Pill, 4 gr., with Aloin, 1-20 gr.
Bottles of 25 and 100, 6d. and 10d.
Blaud Pill, 5 gr., with Strychnine and Arsenious Acid, 1-100 gr. each.
Blaud Pill Compound:—
℞ Pil. Ferrugin. (Blaud), gr. 5; Pulv. Capsici, gr. 1-4 Aloin; Strychninæ; Acid. Arseniosi, aa gr. 1-30.
Bottles of 100, 1s. 3d.

BURROUGHS, WELLCOME & CO.,
LONDON AND SYDNEY.
Cable and Telegraphic Address—"BURCOME, LONDON."

'Emol-Keleet'

A natural powder containing a large proportion of native silicates, employed as a diluent for such potent therapeutic agents as Loretin, Iodoform, Dermatol, Boric Acid, etc., and as a drying and dusting powder.

Its soft, silky texture, soothing influence, and other valuable qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other powders have failed.

Supplied in tins at 9d. each.

BURROUGHS, WELLCOME & CO.,
LONDON and SYDNEY.

'Saxin'
(Trade Mark.)

Is a delicious sweetening agent, about 600 times sweeter than sugar, and has been aptly termed 'the sweetest thing on earth.' 'Saxin' is indicated in diabetes, gout, glycosuria, obesity, etc., because it undergoes no change in the system. A 1/4 gr. 'tabloid' of 'Saxin' is equivalent to one lump of best loaf sugar. A small bottle containing 100 or 200 can be easily carried in the vest pocket.

Supplied at 7d. and 1s. 1d. per bottle.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal*, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

ABSTRACT OF

Lectures

ON

DISEASES OF THE GALL-BLADDER AND BILE-DUCTS.

Delivered at the Royal College of Surgeons of England on March 8th, 10th, and 12th, 1897,

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

LECTURE II.[1]

Delivered on March 10th.

Fistula.—Fistulæ in connexion with the bile passages are by no means uncommon, and their variety is considerable. They result from operation, or from disease, and in the latter case they are due to ulceration resulting from gall-stones or cancer. The fistulous channel may either be direct or indirect; in the former case being caused by an advancing ulcer setting up local peritonitis, and causing adhesion of the gall-bladder or bile-ducts to one of the neighbouring hollow viscera, or to the parietal peritoneum. The extension of the ulcer continuing, a communication is established with the contiguous channel or with the surface. In the latter case, (indirect) the perforation occurs first into an adjoining parenchymatous organ or into a localised abscess, and then into the nearest hollow viscus or on to the surface of the body at some part. A fistula may also arise from a local abscess forming outside the biliary passages around the primary focus of inflammation, and then bursting into the adjoining cavities, which are thus made to communicate. Although the establishment of a fistula is at times dangerous, and at others excessively annoying or uncomfortable, in many cases it forms one of nature's methods of cure in certain forms of disease of the gall-bladder or bile-ducts, and the surgeon in forming a permanent biliary fistula in otherwise incurable jaundice or in making an anastomosis between the bile passages and the intestine for the like purpose, is taking a leaf from nature's book. Many of the fistulæ are mere pathological curiosities, quite undiagnosable, and capable only of being discovered post mortem. Many must form and heal, leaving the patient cured, and thus never be discovered; for contrary to what one might suppose, fistulæ between the bile passages and other hollow viscera, in the majority of cases heal spontaneously, leaving only visceral adhesions; so that the fistulæ are comparatively rarely found post mortem. It would be of value if I could give statistics of the number of times that fistula follows an operation, but this I find is seldom mentioned by operators. I must, therefore, fall back on my own experience. My operations extend to 170 cases, 115 of which were cholecystotomies. I find that in 12 cases there were fistulæ following, but as 5 occurred in my first 10 operations, since which time I have altered my method of procedure, it is fairer to say that 7 fistulæ occurred in 160 cases. Several of the fistulæ were inevitable, as the ducts were strictured; in others they were intentional, as in cancerous obstruction producing jaundice. Where the patients lived—i.e., where the obstruction was due to simple and not malignant disease, they were all cured by further operative means except my first patient, and she might be, but she says the small mucous fistula gives her so little trouble that it is not worth her loss of time to have it remedied.

Biliary cutaneous fistula.—Courvoisier's statistics gathered from reported cases would seem to prove that this is the commonest form of fistula. It may be pathological or post-operative.

Pathological surface fistulæ usually open at the umbilicus, the abscess following the course of the remains of the umbilical vein, but they may form at any part of the abdominal wall, even near the pubes, or on the left side of the abdomen. Calculi of various sizes, from a single one, three inches in diameter, reported by Gutteridge,[2] to multiple small faceted ones, the size of shotcorns, may be discharged in this way, leading to recovery and permanent cure, but until all the calculi are discharged the fistula is liable to remain open. In operating on these cases it is advisable to purify the fistulæ as far as possible and to scrape away all granulations before opening the peritoneal cavity to get at, and clear, the bile-ducts. By adopting these precautions I have had no untoward results in those cases on which I have operated.

Post-operative fistulæ may be mucous or biliary.

Mucous fistulæ are occasionally seen after the operation of cholecystotomy, where the obstruction in the cystic duct has not been overcome, or where that duct is the seat of stricture. In two cases of mucous fistula dependent on stricture of the cystic duct I removed the gall-bladder, effecting a complete and permanent cure. In another case, where a muco-purulent fistula had been discharging at the umbilicus for some months, I followed the channel up to the gall-bladder and found the cystic duct occluded by calculi, which I removed, after which the fistula closed without difficulty. A mucous fistula, as a matter of fact, causes very little inconvenience, as only about 1 oz. of fluid is discharged daily; but if the opening be allowed to close the accumulation produces pain, and it is therefore necessary for a patient under these circumstances either to wear a small tube and a pad of absorbent wool or to submit to operation. The operation of cholecystotomy will not be followed by fistula if the bile-ducts have been cleared, and if the opening in the gall-bladder be sutured to the aponeurosis and not to the skin. Since I modified the operation of cholecystotomy in this way, which I did in my eleventh operation, I have never known a fistula to follow when the bile-ducts have been cleared.

Biliary fistula following on operation is quite a different matter from mucous fistula, as, although in some cases it is compatible with good health, the inconvenience caused by thirty ounces of bile flowing from the fistula daily, produces so much discomfort that in all the cases which have come under my notice the patients have preferred to accept the risks of operation rather than to retain their disability. The treatment of biliary fistula should, where possible, be effected by removing the cause; but as in certain cases this is impracticable or impossible other means have to be considered. If the ducts be clear and the fistula be small the application of the actual cautery to the margin of the fistula will frequently result in its closure. That failing, the method I adopted in Case 116 may be followed, of opening the abdomen, detaching the gall-bladder, and suturing the opening. Or the less severe method may be tried first of dissecting the fistula with its peritoneal covering intact from the skin margin, afterwards doubling in the mucous edges, suturing them accurately, and over this applying one or two layers of buried sutures before bringing together the skin. Where, however, the ducts cannot be cleared and the gall-bladder is large enough to permit it. the operation of cholecystenterostomy may be performed. I believe I was the first to carry this operation out in a case of biliary fistula on Jan. 14th, 1888, and the patient is at the present time in excellent health, doing duty as a maternity nurse. I have since performed it on four occasions for fistula, each time with success, so that in such cases I feel I can recommend it as a safe and efficient method of treatment. If the fistula be dependent on gall-stones or fragments in the ducts the ducts may be syringed through daily with olive oil or with a 0·5 per cent. solution of sapo animalis, as recommended by Dr. Brockbank; or a solution of turpentine in ether may be used. This is easily done by employing a small, flexible catheter, which is passed through the fistula as far as it will go without force. To the end of this a syringe is affixed and the medicament steadily syringed directly on to the obstruction, the syringing being repeated night and morning for a time.

Biliary intestinal fistulæ, as might be expected from the contiguity of the gall-bladder to the duodenum and colon, are the most common, and as a rule they are due to ulceration produced by gall-stones. Usually the ulceration proceeds quietly and produces very few symptoms until the gall-stone sets up obstruction in its passage down the intestinal canal. If the fistula is between the gall-bladder and duodenum, "the most common variety," the whole length of the intestinal canal has to be traversed by the concretions; hence such cases are found to be more frequently

[1] Lecture I. appeared in THE LANCET of May 29th, 1897.

[2] THE LANCET, June 8th, 1878, p. 851.

Hosted by Google

associated with obstruction than when the fistula is between the gall-bladder and colon, for in the latter case the passage to the anus is accomplished without difficulty, though occasionally the concretions may lodge in the cæcum and cause trouble. When a gall-stone is impacted in the common duct just before entering the duodenum ulceration and perforation of the duct are apt to occur, the concretion thus escaping into the duodenum by an enlargement of the ostium of the common bile-duct from ulceration or sloughing. Roth, who has paid special attention to this condition, found it five times in twenty-five cases of biliary fistula. These gall-stones are usually smaller than those causing gall-bladder intestinal fistula, are seldom larger than filberts, and do not often cause intestinal trouble. Biliary gastric fistula is less common than might be thought, for the pylorus is not infrequently adherent to the gall-bladder. I have only one case to advance from my own experience, and in that instance the vomiting of gall-stones made the diagnosis probable, though the complete recovery of the patient, a woman of fifty, rendered it impossible to be absolutely certain that the surmise was correct. Murchison was of opinion that all vomited gall-stones must have entered the stomach through a fistula. In one case Jeaffreson [3] found such a fistula post mortem, a gall-stone having been vomited some time before.

Intestinal obstruction.—Intestinal obstruction from gall-stones is such a distinct complication of cholelithiasis, calling for special treatment, that I think it will not be beyond my province to consider it, and as the chief variety of obstruction is necessarily associated with fistula it seems to me convenient to consider it here. So much has been written about obstruction from gall-stones that at first sight it might seem to be a somewhat common ailment; such, however, is not the case, as may be gathered from the fact that on inquiring of the registrars and pathologists I found only four such cases had been treated during a period of twelve months in some of the largest hospitals in the kingdom, representing 80,000 in-patients, and several hundred thousand out-patients attended to during the same time. Again, only one case, according to Dr. Brockbank, had occurred in the Manchester Royal Infirmary between 1883 and 1893, during which time 50,000 in-patients had been treated. There are clearly four classes of obstruction of the intestines depending primarily on gall-stones, though by intestinal obstruction from gall-stones is usually understood the impaction of a large concretion in some part of the intestinal tract producing a mechanical block. The varieties are: 1. That due to local peritonitis in the gall-bladder region, leading to paralysis of the bowel. The symptoms may be so severe as to resemble strangulation by a band or acute intussusception. The diagnosis will not, as a rule, be difficult, as the history of the occurrence of previous attacks of spasms, though not of necessity followed by jaundice; the similarity to these of the commencement of the attack in question; the severe and persistent pain, at first localised to the right side of the abdomen; the absence of distension at the commencement, and then the occurrence of distension on the right side only, becoming general later; the lateness of the onset of fæcal vomiting, and only after continued retching; the existence of collapse at an early stage owing to the severity of the pain, which is usually relieved by a morphia injection; the usual absence of visible peristalsis; and, lastly, the onset of jaundice if the concretions have reached the common duct, afford so much guidance that error will not often occur, especially if the patient be a woman of middle or old age. These cases will, as a rule, yield to general and medical treatment, and it will only occasionally be necessary to resort to operation during the seizure if the symptoms are not subsiding, though subsequent surgical treatment may be required. 2. Volvulus of the small intestine, dependent on the violence of the colic caused by an attack of gall-stones, or on the contortions induced by the passage of a large concretion through the small intestine, is probably uncommon. The following are abbreviated notes of one of two cases that have come under my personal observation.

CASE 1.—Acute intestinal obstruction in a woman, aged sixty-eight years, operated on Nov. 12th, 1890, by laparotomy, on the eighth day of the obstruction, a volvulus of the small intestine being discovered and untwisted. The bowels were moved by enema on the sixteenth day after onset of obstruction and the eighth day after operation, and a large gall-stone three inches in circumference was passed, this being manifestly the cause of the obstruction, and, secondarily, of the volvulus. The patient returned home on the twenty-sixth day, and remained quite well when heard of a year subsequently.

Diagnosis.—In this class of cases (volvulus) a positive diagnosis is, probably for the most part, out of the question, except after the abdomen is opened, as volvulus of the small intestine is an extremely rare event, and we know that a large gall-stone may quietly ulcerate its way into the gut without any preliminary warning, the symptoms only arising when the concretion is passing through the small bowel.

Treatment.—In this class, operation holds out the only hope of success.

The fourth class is characterised by obstruction coming on after the original cause has disappeared and depends on adhesions left by the local peritonitis due to gall-stone attacks, or on narrowing caused by the healing of a fistulous opening through which a large gall-stone has made its way into the intestinal tract. Dr. Brockbank refers to a case in the Transactions of the Pathological Society of London, 1852, in which there was chronic inflammation and thickening of the ileum and cæcum, with destruction of the ileo-cæcal valve, these being dependent on gall-stones found in the thickened and ulcerated bowel. The bowel was dilated above the obstruction and much contracted below. The patient suffered from chronic diarrhœa for three years, which alternated with attacks of obstruction.

The third class is the most important variety of obstruction dependent on gall-stones, and is the one furnishing, not only the greatest number of cases, but a considerable number of museum specimens. It is dependent on the mechanical obstruction and damage to the bowel produced by the passage of a large concretion through the intestine.

In a paper read before the Royal Medical and Chirurgical Society in 1894 I related notes of cases illustrating this condition. It is astonishing how few unsuccessful cases are reported, yet we know that the mortality of these operations has been considerable. In making a study of the reported cases, and especially of museum specimens, one cannot help feeling astonished at finding fatal obstruction depending on quite small concretions and the comparatively easy passage of very large gall-stones. Schuller (Strasburg, 1891), in reviewing 139 published cases, found that the subjects were women in 74·3 per cent., and of these 75 per cent. occurred in women over fifty years of age, though instances were found from eighteen to ninety-four years of age. Lobstein (Heidelberg) [4] gives the most common age as between forty and sixty years. It is a curious fact that although the calculi usually produce intestinal trouble within a few days of reaching the intestine, in some cases they may remain in the bowel for long periods—e.g., in a case under the care of Mr. Eve,[5] ten years, and in one under the care of Mr. Thomas Smith [6] probably fifteen years. In Courvoisier's elaborate statistics, out of fifty-three cases examined, he gives the site of obstruction as in 21·4 per cent. in the duodenum and jejunum; in 65·4 per cent. in the ileum; in 10 per cent. at the ileo-cæcal valve; and in 2·4 per cent. in the sigmoid flexure. The disease is a peculiarly fatal one—of 280 cases collected by Schuller, Dufort, and Courvoisier 156 died, or 52 per cent. Kermisson and Rochard,[7] of 105 collected cases, gave the mortality as 50 per cent. The cases that recovered lasted on the average eight days, those that died ten days, but the duration of obstruction may vary from one to twenty-eight days. A case reported by Sargent [8] actually died apparently from the intensity of the pain, after symptoms lasting only half an hour. Lobstein [9] collected 92 cases; of the 61 not operated on 32 recovered, the remaining 29 died from peritonitis or exhaustion; of the 31 operated on 12 recovered, but as many of the 19 which died were moribund when operated on, their death cannot be charged to operation. As more than one large concretion may be present in the gut at the same time, in a few cases the symptoms of obstruction have been known to recur once, twice, or three times after the first concretion has been parted with. Dr. Maclagan [10] has described two cases of this kind, and Mr. Clutton [11] has described another in which he operated successfully within twenty-four hours of the

Hosted by Google

onset of the second seizure and manipulated the stone through the ileo-cæcal valve. The symptoms are those of acute intestinal obstruction from other causes, with early fæcal vomiting and severe abdominal pain. The higher in the gut the impaction the more violent, as a rule, will be the symptoms. The obstruction can only very rarely be felt through the abdominal walls. Although in one of my cases I was able to make a probable diagnosis from the history of previous gall-stone attacks extending over several years, yet in many cases there is absolutely no previous history to guide one, and it is quite impossible to say whether or not the attack is one dependent on the cause in question or on a volvulus, or band, or internal hernia, which, if left, must inevitably lead to death, and that speedily. The age and sex, together with the history of chronic dyspepsia and pain in the hepatic region, are, however, well worth bearing in mind as well as the early and persistent vomiting and visible peristalsis limited to the small intestines.

Treatment.—If the diagnosis could always be made with certainty I think this is a condition in which medical and expectant treatment might be fairly given a trial, since we have ample evidence of large gall-stones having safely passed without other treatment. But we must not forget that 52 per cent. of cases treated on medical and expectant lines are fatal, and although surgery has not yet shown a much greater percentage of recoveries it is because surgical means are frequently only resorted to when the case is hopeless and after all other means have been tried. When it is borne in mind that there are no symptoms peculiar to this form of obstruction, and that the course pursued by an obstruction by a band or by an internal hernia may be exactly the same as in gall-stone obstruction, the surgeon who waits beyond the period when an operation may be undertaken with every hope of success is incurring a very serious responsibility. With regard to the method of treatment after the abdomen is opened and the cause found, if the gall-stone can be easily crushed through the intestinal coats, without too much force being required, so much the better, but that failing enterotomy should be performed, as it can be done very quickly and with very little damage to the bowel. Should the patient be too ill to bear a search being made for the obstruction, enterotomy, or perhaps short circuiting, might be performed in order to give temporary relief, the cause of the obstruction being afterwards removed, if not passed naturally. As to when operation should be performed, that is part of a general question which each surgeon will have to answer for himself in every individual case, as no definite rule can possibly be formulated which will apply to all cases. The surgeon will, as a rule, not be called in before decided symptoms of intestinal obstruction have manifested themselves and until medical means have been fully tried; in such cases it would seem to me to be idle waste of time to delay surgical intervention until the patient is so exhausted that operation is only undertaken as a *dernier ressort*, when the subject is almost moribund. If, however, the case be seen at an earlier stage morphia will have to be given to relieve the pain, and I have usually recommended extract of belladonna in quarter-grain doses every four hours, the stopping of all food by the mouth, and the administration of one or more large syphon enemas, given slowly with the buttocks elevated. If relief does not speedily follow and the diagnosis is not clear, chloroform anæsthesia may assist in two ways. In the first place it enables a thorough examination of the abdomen and at times a diagnosis of the cause to be made; and, secondly, the manipulation, if made methodically, may reduce a hernia or volvulus or may possibly help onwards an obstruction. This failing and the symptoms persisting I should operate, and at this comparatively early stage I feel sure with every prospect of success.

Tumours of the gall-bladder and bile-ducts.—If by tumour be understood new growth, then tumours of the gall-bladder and bile-ducts are not common; but if we accept the usual interpretation of the term and include all enlargements as tumours we shall find them by no means rare.

Distension of the gall-bladder.—A tumour of the gall-bladder through distension with bile must be a rare phenomenon, though it is sometimes described as an accompaniment of a gall-stone attack where the concretion is impacted in the common duct; even in such a case it must be a symptom of short duration, since if the impaction be complete, the bile speedily becomes absorbed and gives place to distension by mucus. A perceptible tumour formed by distension with gall-stones is also rare, unless it happens that some have become impacted in the cystic duct, when a gradual enlargement from the retained mucus will follow. I have removed as many as 750 gall-stones from a gall-bladder during an operation, and yet that gall-bladder could not be felt as a distinct tumour. Occasionally a large single gall-stone may form a hard perceptible swelling below the liver, but such is very rare. Calcified gall-bladder, which is due to cholelithic catarrh, may lead to the formation of a hard, rounded, painless tumour, and this is evidently not very uncommon if we may judge of its frequency by specimens in the museums.

Hydrops and dropsy of the gall-bladder are terms used to denote distension of the gall-bladder by mucus. It may result from any obstruction in the cystic or common ducts, whether due to gall-stones, stricture, or growth in the ducts or to cancer of the head of the pancreas, provided that the gall-bladder has not atrophied as the result of previous gall-stone irritation. It is due to the gradual accumulation of the natural secretion of the mucous lining, and may attain such a size as to be mistaken for an ovarian cyst, as in cases reported by Mr. Lawson Tait and by Professor Kocher, though it is uncommon to find the tumour of greater size than from 15 to 20 oz. capacity. Not only may the cavity be dilated, but its walls may be enormously hypertrophied so as to form a distinct tumour. If the obstruction be associated with inflammation the contents of the gall-bladder may become purulent and an empyema of the gall-bladder result, the symptoms and complications of which I have already considered.

Signs.—Enlargements of the gall-bladder may vary from a tumour just perceptible to the touch to one of such a size as almost to fill the abdomen, though one of greater size than a large pear is exceptional. The same tumour may also vary in size at different times, this variation being frequently found in gall-stone obstruction. The symptoms of tumour of the gall-bladder depend for the most part on the cause, and in consequence vary considerably, at times being slight and unimportant, at others both urgent and serious. The gall-bladder, as a rule, enlarges downward and forward in a line which, drawn from the ninth or tenth costal cartilage, crosses the linea alba a little below the umbilicus, but the position of the tumour varies with the size of the liver. When that organ is of normal size the neck of the gall-bladder is opposite the ninth costal cartilage, whereas when the liver is enlarged the gall-bladder will be pushed down so that the neck of the tumour may be opposite to, or even below, the umbilicus. If uncomplicated it will have a smooth, rounded, and pear-shaped outline, the larger end being below, quite free, and movable from side to side, the upper end being fixed and passing under the lower margin of the liver at the fissure of the gall-bladder. A distinct sulcus between the liver and gall-bladder is nearly always perceptible to the touch if the warmed flat hand be laid over the right side of the abdomen and the patient be told to take a deep breath, when the tumour and the liver will descend together and pass under the fingers. Bimanual palpation will frequently throw additional light on the case, the right hand being placed in front of the abdomen and the left over the right loin, making gentle pressure forwards. In other cases additional information may be obtained by placing the patient in the genu-pectoral position and passing the flat hands round the abdomen from behind, when a tumour of the gall-bladder will rest distinctly on the hand, and on deep inspiration it can be felt to move just beneath the abdominal walls, the upper surface of the liver also being in this way capable of palpation. The swelling is, as a rule, far too tense and hard for fluctuation to be elicited, though at times this sign may be obtained. In some of the larger swellings a thrill almost like the hydatid fremitus may be felt on gently flicking the tumour with the finger-nail. Percussion by no means always elicits dulness coextensive with the tumour, especially if the surrounding intestines be distended, so that dulness on percussion is a very variable sign, and palpation will be found more reliable. Inspection of the abdomen with the patient recumbent will at times show the tumour descending on respiration, but this sign is usually only to be observed in thin patients and in cases uncomplicated with inflammation. When there is inflammation and matting of the adjoining viscera a fixed swelling may be seen over the right hypochondrium, with dulness on percussion and marked tenderness. Tenderness on palpation is a variable symptom, depending on the presence or absence of local peritonitis, it being, as a rule, absent in uncomplicated enlargements of the gall-bladder. Jaundice may complicate tumours of the gall-bladder, both being dependent on the same cause—a

blocking of the common bile-duct. Although not absolutely pathognomonic of malignant disease, the combination should always raise a suspicion of cancer of the head of the pancreas or of the liver or bile-ducts, especially if it be associated with great loss of flesh and strength and with absence of characteristic gall-stone pain. I have observed in a considerable number of cases distension of the gall-bladder with jaundice to be associated with malignant disease, but much less often the combination of tumour, jaundice, and gall-stones, the explanation of this apparent anomaly being that the gall-bladder frequently becomes diminished in size and adherent as the result of gall-stone irritation, so that when the common duct becomes blocked by a calculus jaundice occurs without distension of the gall-bladder, as it is unable to expand. If, however, the common duct becomes blocked by gall-stones before the gall-bladder has contracted and formed adhesions there may be the combination of jaundice and tumour. If the common duct be blocked by tumour, the gall-bladder, not having been subjected to irritation, and therefore not having become contracted, will at once distend. Thus in malignant disease of the head of the pancreas we find the usual combination of jaundice with tumour of the gall-bladder. Gall-bladder tumours usually contain mucus, occasionally pus, rarely bile. In all cases when the cystic duct is obstructed and inflammation has not followed, mucus alone is present, though when inflammation co-exists pus or muco-pus may be found. In obstruction of the common duct by gall-stones the gall-bladder, though usually contracted, may be found distended by bile at first and mucus later; though, as a rule, the swelling subsides more or less rapidly and no tumour persists, the gall-bladder shrinking. When the obstruction becomes absolute, as in malignant disease of the head of the pancreas, the tumour formed is persistent, and although the block is in the common duct, bile soon ceases to reach the gall-bladder, and the tumour is always found to contain mucus This occurs on account of the backward pressure preventing the excretion of bile, which, though formed by the liver-cells, is immediately taken up by the lymphatics.

Diagnosis.—Tumours of the gall-bladder may have to be diagnosed from:—(1) Movable right kidney; (2) tumour of the right kidney or of the suprarenal capsule; (3) tumour of the intestine or fæcal impaction; (4) tumour of the liver; (5) pyloric tumour; and (6) abnormal projection of the liver. The diagnosis of enlargement of the gall-bladder from movable right kidney is, as a rule, easy in thin persons; but in those who are stout or have tense or strong muscular abdominal walls difficulties may and do arise, which can, however, usually be overcome by examination under an anæsthetic. In the case of renal tumour as well as in movable kidney, by distending the intestine with gas the kidney will be pressed back into the loin, but the gall-bladder will be pushed up towards the liver and made more prominent. The last test is usually also sufficient to enable a diagnosis to be made between a distended gall-bladder and a tumour of the right suprarenal body; but this is not always reliable, as in a case I saw with Mr. Kebbell, of Flaxton, Ziemmsen's test pushed the swelling upwards, and on performing abdominal section a sarcoma of the suprarenal capsule was found and removed.

In tumour of the intestine or of the pylorus the associated stomach or bowel symptoms are usually sufficient to enable a diagnosis to be made, but when in doubt distension of the stomach or bowel with gas will help to clear it up, or examination under an anæsthetic will afford assistance. Tumour of the liver itself, either cancer or hydatid disease, may be almost indistinguishable from one of the gall-bladder, though the presence of nodules in the liver, with the history and other symptoms of malignant disease, will usually be sufficiently distinctive in cancer, while the less localised and more generally fluctuating swelling, together with the longer history and absence of pain, will distinguish hydatid tumour. It should not be forgotten that the right lobe of the liver may have an abnormal projection, either in the site of the gall-bladder or to the right of that position, which may at first be mistaken for an enlarged gall-bladder; but the absence of symptoms, together with careful bimanual palpation, will usually enable a correct diagnosis to be made; and, as Professor Riedel has pointed out, the gall-bladder may frequently be felt apart from the swelling or at the top of it. Puncture with an exploring syringe would, of course, give valuable information, but this should not be lightly undertaken, as it is not devoid of risk, death having occurred on more than one occasion as a direct result of this apparently slight operative procedure. If it is decided to employ an exploring needle the aspirator should always be used, in order that the tense cyst may be completely emptied, otherwise leakage from the puncture is almost certain to occur. After the abdomen has been opened I have seen a puncture of the tumour by a small exploratory syringe to pour out fluid in a forcible stream, showing what would have occurred had the puncture been made through an unopened abdomen. In case of doubt, especially where the symptoms demand interference, exploration of the tumour through a small abdominal incision can be undertaken with very little risk and at the same time further treatment where called for can be carried out. Of the tumours dependent on new growth, cancer of the gall-bladder is the most important, innocent growth, except of inflammatory origin, being extremely rare, unless it be true, as Zenker suggests, that an adenoma first develops in the gall-bladder, and subsequently becames transformed into adeno-carcinoma. Dr. Rolleston[12] reports a case in which this sequence apparently occurred in the bile-duct of a woman from whom a papilloma was removed, the growth being in immediate contact with a gall-stone. After some months she returned with a growth in the same region, presumably malignant. Cancer of the gall-bladder is by no means frequent, and as a primary affection is somewhat rare. Musser collected all the reported cases in the *Boston Medical and Surgical Journal* of Dec. 15th, 1889, and Dr. Rolleston published an extremely interesting paper on the subject in the *Medical Chronicle* of January, 1896. It is usually secondary to gall-stones or to cancer of adjoining organs, and in the latter case is not amenable to surgical treatment. The very frequent association of cancer of the gall-bladder with gall-stones is an undoubted fact, and in all probability there is a connexion between the two diseases. Zeurkert[13] found gall-stones in 85 per cent. of cancers of the gall-bladder, and Musser, from an analysis of 100 cases, gives the proportion associated with gall-stones as 69 per cent., which may, however, be an under-estimate, as it is well known that gall-stones may produce serious irritation and then pass into the alimentary canal, so that their effects may remain, although the cause may not be discovered. According to Schroeder, 14 per cent. of all cases of gall-stone patients suffer at some time from cancer of the biliary passages, and Naunyn is of opinion that half the cases of chronic jaundice diagnosed as cholelithiasis are complicated with cancer or are due to cancer alone. This latter statement is of extreme importance, since operation in the presence of cancer and chronic jaundice is very fatal. The two theories which have been current to explain the co-existence of gall-stone with cancer of the liver are, first, the "irritation" theory, that gall-stones are formed first, and by acting as foreign bodies set up irritation which leads to malignant growth; and second, the "concentration" theory, that gall-stones arise as a secondary result from stagnation of bile in the ducts caused by their obstruction from malignant growth. Mr. C. Beadles,[14] in a paper read before the Pathological Society of London, stated that out of 100 post-mortem examinations at the Cancer Hospital 4 were cases of primary carcinoma of the liver, and all had calculi in the gall-bladder; 36 had secondary carcinomatous growths in the liver, but there were no gall-stones present in any of them. Of 9 cases of primary carcinoma of the bladder at Colney Hatch Asylum 5 were males and 4 females, and gall-stones were present in 7, being absent in 1 male and 1 female. These facts support the theory of irritation. Simple growths in the gall-bladder are not of great clinical importance except as precursors of malignant disease.

Symptoms and signs.—If the growth be primary there will be the history of a more or less rapidly growing tumour developing under the right costal margin, accompanied at first by a sense of discomfort, shortly changing to pain, which is often worse at night, and which, though at first localised to the right hypochondrium and epigastrium, usually, before great advance has been made, extends round the side to the right infra-scapular region. When the enlargement is first noticed it is felt as an egg-shaped swelling beneath the liver, descending on aspiration. The tumour is hard to the touch and very slightly or not at all tender to pressure. At a later stage it becomes more fixed and more diffused, and nodules may develop and be felt on its superficial surface. As the growth

extends it invades the liver and sometimes the duodenum and stomach. Dissemination is rare. According to the invasion or not of the hepatic or common bile-ducts, so will be the presence or absence of jaundice, but in nearly half of the cases some degree of icterus will be found as the disease advances owing to the presence of catarrh of the bile-ducts. Interference with the action of the bowels, even to partial or complete obstruction, at times occurs. General failure of health, continued wasting, with loss of strength, ascites, and marked cachexia, characterise the later stages. Perforation may occur and hasten the end by the onset of general peritonitis. If gall-stones be present there will be the usual antecedent history of cholelithiasis. Where gall-stones with jaundice complicate cancer of the gall-bladder exacerbations of pain will usually be accompanied by rigors and fever, "ague-like attacks" with an intensification of the icterus, and in such cases petechiæ in the skin with hæmorrhage from the nose and rectum usually supervene.

Diagnosis.—Cancer of the gall-bladder may usually be diagnosed by the progressive character of the disease and by the presence of the characteristic hard tumour; but it is by no means always easy to diagnose cancer from a tumour formed by matted intestines due to local peritonitis in the neighbourhood of the gall-bladder. When in doubt exploration is probably the best method of settling it, as at the same time treatment may be carried out.

Treatment.—The alleviation of symptoms, especially of pain, by sedatives is practically all that can be done except in those rare cases where the disease is limited to the gall-bladder, when cholecystectomy may be performed. In only one case out of several on which I have operated have I found the disease sufficiently limited to permit of excision, and even in that instance I had to perform partial hepatectomy.[15]

Tumours of bile-ducts.—Tumours of the bile-ducts, *per se*, only occasionally form a projection so large as to be distinguished through the abdominal walls. Tumour, however, in such cases is as a rule present sooner or later on account of the obstruction in the ducts and secondary distension of the gall-bladder. The common duct has been found dilated to such a size as to form a cystic tumour presenting all the characteristics of a distended gall-bladder, the gall-bladder itself being atrophied. In two cases of this kind I performed, in the one choledochostomy after cholelithotrity, the patient making an excellent recovery; in the other choledochenterostomy after cholecystectomy, the patient also doing well. Although hitherto the results of choledochostomy have not always been favourable, probably in consequence of the fact that extreme distension of the bile-duct is often accompanied by infection of the biliary passages, it would be well to reserve our opinion as to the prospects of the operation until we have more experience of it. Very little information can as yet be obtained on this subject, cases of distension of the common bile-duct being very rare, and those in which surgery has intervened still more exceptional. An interesting case is reported by Mr. W. P. Swain in THE LANCET of March 23rd, 1895, in which he connected a dilated bile-duct to the jejunum by one of Murphy's buttons. The size of the tumour, which occurred in a girl aged seventeen years, and which was associated with gall-stones, may be gathered from the fact that over seven pints of fluid were withdrawn from it at the time of operation. Three months after the patient was progressing satisfactorily except for an occasional rise of temperature, and for the fact that the button had not been passed.

The new growths found in the bile ducts may be simple or malignant. Of the malignant we must take into consideration the two classes, primary and secondary, the former arising most frequently as the result of gall-stone irritation, the latter by extension from neighbouring organs. Papilloma is probably an earlier stage of cancer and is rare. These growths are usually found between the ages of fifty and sixty years, and, unlike cancer of the gall-bladder, where 75 per cent. of cases occurred among women, the disease attacks both sexes equally. If forming in the cystic duct jaundice will be absent at first, only coming on when the growth advances so far as to pass into the common duct and obstruct the passage of the bile, or if, as is not uncommon, catarrh of the bile ducts supervenes. The gall-bladder enlarges at an early stage, and this will probably be the earliest sign; pain may be absent unless gall-stones exist, when the usual spasmodic pains will occur so long as the muscular coat of the gall-bladder retains its contractile power. When the growth is in the common duct jaundice comes on at an early stage and persists throughout, the liver gradually increasing in size and the gall-bladder also enlarging ultimately. Suppurative cholangitis is apt to supervene, the case then taking on a more acute course and being accompanied by fever, ague-like attacks, and rapid loss of flesh and strength. Needless to say, the disease is uniformly fatal, though operation may delay the final catastrophe. Cancer of the ampulla of Vater has received some attention from M. Hanot,[16] M. Durand-Fardel,[17] M. Rendu, and Dr. Rolleston.[18] Two forms at least are described, one arising from the intestinal walls of the ampulla and the other from the orifice of the common bile duct and the pancreatic duct. They are characterised by intermittent jaundice, wasting, and cachexia, but as a rule pain is absent. It was probably first described by MacNeal[19] in 1835, and later by Stokes[20] in 1846.

Diagnosis.—The diagnosis of new growth in the bile-ducts from gall-stones is practically impossible, as the symptoms are the same, and in fact the two frequently co-exist. The absence of pain in some cases and the rapid deterioration of health may afford a little help, but in some cases the pain may be as acute as in cholelithiasis. Cystic dilatations of the bile ducts are often indistinguishable from enlargements of the gall-bladder, for which they are usually mistaken; but they may resemble a cyst of the pancreas or a hydatid tumour of the liver. As, however, the treatment in all these conditions is abdominal section, no harm will be done if the diagnosis is only completed when the abdomen is opened.

Treatment.—The operative treatment of these tumours is in its infancy and has thus far not proved uniformly satisfactory. Any growth should be removed if possible, but where that is impracticable the dilated gall-bladder or ducts may be opened and drained, or, better still, drained into the duodenum or jejunum by means of one of Murphy's buttons. If the cause be a removable one, such as a gall-stone, it should be taken away. Choledochostomy has not yielded good results in cystic dilatation of the bile-ducts, my own case being, I believe, the only example of recovery after the operation, whereas the experience of performing an anastomosis between the cyst and the intestine, though as yet slight, has been so satisfactory as to establish its claim to being considered the best method of treatment.

CRIME IN WILTSHIRE.—The report issued by the chief constable of Wiltshire and presented at the meeting of the standing joint committee last week showed that 727 persons had come under the cognisance of the police during the past quarter, of whom 26 were committed for trial, 495 summarily convicted, 71 quasi-criminal cases, and 135 discharged. There had been an increase of 36 in the numbers of persons proceeded against.

UNIVERSITY OF CAMBRIDGE.—The Vice-Chancellor for the next academical year will be a Doctor of Medicine, Dr. A Hill, Master of Downing College, and Lecturer in Advanced Human Anatomy, having been elected to the office on June 1st. The Deputy Professor of Pathology, Dr. A. A. Kanthack, announces courses in Pathology, Bacteriology, and Morbid Anatomy and Histology, during the ensuing long vacation, beginning on July 7th and 8th. Some of these will be adapted to the requirements of candidates for the Diploma in Public Health. It is proposed to confer honorary degrees on the Archbishop of Canterbury, the Marquess of Lansdowne, Lord Russell of Killowen, Chief Justice Way, a number of the colonial premiers now in England, Sir G T. D. Goldie, Sir John Kirk, Sir Arthur Arnold, and Sir W. H. White. On May 27th the following medical and surgical degrees were conferred:—M.D.: H. Walsham, M.A. Caius, and N. L. Hood, M.A., M.B. and B.C. Downing: L. T. R. Hutchinson, B A. Trinity, W. McDougall, B.A. St. John's, L. T. Giles, B.A. St. Peter's, R. D. Parker, B A. Caius, and W. B. Heywood, B.A. Emmanuel. M.B. only: W. M. Sing, M.A. Christ's.

ABSTRACT OF

A Clinical Lecture

ON THE

PROPER TREATMENT OF CUT-THROAT WOUNDS BY IMMEDIATE SUTURING OF ALL THE DIVIDED STRUCTURES.

Delivered at the Middlesex Hospital on May 11th, 1897,

BY HENRY MORRIS, M.A., M.B. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO THE MIDDLESEX HOSPITAL.

GENTLEMEN,—I have on two occasions during the last nine years advocated in this theatre, in lectures which have been published in the medical journals, the treatment of cut-throat wounds by the application of immediate sutures to all the divided tissues. I first made the suggestion in 1888.[1] I afterwards related several cases so treated, and fully discussed the subject in a clinical lecture delivered in 1892.[2] That less attention has been paid to this treatment than its success and the benefit it affords to patients demand appears from the uncertain and indefinite way in which the use of sutures is mentioned in the latest and most consulted text-books on surgery. And that it is not yet taught in the medical schools as being the proper treatment has been impressed upon me by reading the replies to a question recently set on this subject at one of the examinations. Yet surely a method which shortens convalescence to one-third or one-quarter, or even less, of the time required by leaving the wound open; which enables the patient to talk and swallow naturally within a very few hours after the injury, instead of being fed for days, or even for a week or two, by means of the œsophageal tube; which does away with the troublesome cough and the abominable discharge of food, saliva, and bronchial secretion through the wound; which permits of a dressing being retained over the wound unchanged for days together; and which is not followed by any of the old risks of incurvation of the edges, of stricture, or of fistula, is a worthy substitute for the tedious, distressing, and disgusting open method, which was only tolerable as long as surgeons were less particular about their hæmostatics, less careful about drainage, and less punctilious about the asepticity of their dressings than nowadays.

As I stated in 1892, "I have ventured to depart from the time-honoured practice of leaving cut-throat wounds open to heal by granulation and cicatrisation, and have sought, by the liberal employment of buried and superficial aseptic sutures, to bring about immediate union." All the old objections[3] to close union of the divided structures are groundless, for why should primary union be more rare in wounds of the neck involving the larynx or trachea than elsewhere? There is no more difficulty here than elsewhere in perfectly controlling hæmorrhage and in preventing suppuration; and if this is so, wherein lies the risk of blood or pus getting into the air passages? As a matter of fact, these wounds of the throat, like wounds of the face and mouth, of the abdominal parietes and peritoneum and the abdominal viscera, heal very rapidly and securely if given a chance to do so; and we may reckon on the air passages, as we do on the parietal peritoneum in abdominal wounds, being securely closed long before suppuration, if it occurs at all, affects the cellular tissue planes outside. Of course, to obtain a rapidly favourable termination in these suicidal wounds proper care and due precautions must be exercised in the application of the sutures, and strict attention must be given to the general state of the wound before inserting them. The patient should be put under an anæsthetic, and all, even quite small, bleeding points should be secured; scrupulous cleanliness of the parts must be obtained by the usual aseptic and antiseptic means. This done the cut edges of the wind-pipe should be adjusted by fine silk sutures, which should not penetrate the mucous membrane. The sutures should be applied close enough to one another to prevent any portion of the edges of the wounded air passage from flapping or swaying backwards and forwards with the ingress and egress of air. The sutures should pass through or around the rings of cartilage if necessary. Then the divided edges of the fascia covering the trachea or larynx should be united with separate sutures. This is a very important step in the procedure, and great care should be given to it, because the close union of this fascia affords additional security to the closure of the air tube, and helps in preventing any escape of air between the sutures uniting the edges of the wind-pipe. Next, in like manner the infra-hyoid muscles, the deep fascia overlying these muscles, and the skin respectively must be properly joined. A very small drainage-tube may be inserted between the edges of the skin on each side near the outer extremities of the superficial wound, but not near the middle line of the trachea. Finally, it is very necessary to keep the head sufficiently flexed, and the head and neck very fixed, during the period requisite for firm healing of the wound. In applying the sutures it must be borne in mind that the tissues when fairly cut across have a very strong tendency to retract, but the skin less so than the muscles, fasciæ, and air tube. If, then, we have half an inch separation of the skin edges there will be a gap of an inch or more between the cut ends of the other structures. Consequently the lower ends of these structures must be sought for and drawn up from below and behind the cut edge of the skin.

Too much care cannot be given to the accurate adjustment of the edges of the wound in the air tube, and if at any point there is difficulty in completely closing it, and the surgeon doubts whether he has made the tube entirely air-tight, he should with all the more care bridge over this point of the windpipe by additionally secure union of the deep layer of fascia.

Nothing, I admit, can be more unsurgical, besides being very harmful to the patient, than to draw together the cut ends of the wounded windpipe with one or two sutures, in order to hold up the trachea, but without sufficiently closely uniting them to prevent air escaping freely from the air passage; and then, without uniting fascia and muscles, to close the skin incision by continuous suture, and hermetically seal it with collodion and cotton wool. Such a plan must necessarily be followed by dangerous emphysema, and is about as rational as it would be, in a penetrating wound of the abdomen attended with division of the bowel, to draw together the cut ends of the intestine by a few sutures insufficient to make the union watertight, and then to stitch together the skin only of the abdominal wall, and smother the wound with collodion and wool.

The occurrence of surgical emphysema from insufficient and improper suturing is no more an argument against the use of sutures in cut-throat wounds than is extravasation of fæces into the peritoneal cavity from a similar cause an argument against the complete and water-tight suturing of the two ends of recently divided intestine. The man whose case is subjoined was certainly put into a condition of very great suffering and danger by the method of suturing adopted prior to his admission into hospital; from this danger he was saved by the prompt removal of the skin sutures by my house surgeon, Mr. Myler. A few hours after the wound had been reopened, and the patient had thereby recovered from the worst effects of the emphysema, he realised the further relief afforded him by the proper readjustment and close union by sutures of each of the divided structures. He was able to talk as soon as he had recovered from the anæsthetic, he took liquid food well and freely the same evening, he enjoyed a good night's rest, and within a few days was taking an ordinary diet. Though his convalescence, on account of the emphysema, was perhaps not quite so rapid as that of other patients whom I have treated in the same way, yet he was out of bed on the twelfth day and discharged from the hospital quite well on the sixteenth day after the injury. The following is an account of the case upon which the above remarks were based, and is taken from notes made by Mr. J. W. Glenton Myler, house surgeon.

On April 10th, 1897, a man, aged forty-four years, was admitted into Broderip Ward, Middlesex Hospital, in a state of collapse. He was a well-nourished man. He was stated to have been drinking heavily lately, and in a moment of alcoholic frenzy he had made an attempt on his own life. The act was committed about 12.30 P.M. with a razor.

When admitted, about 1.15 P.M., he was breathing rapidly, was cyanosed, and made several disconnected remarks. He was in great pain and pointed to his chest as being its chief seat. His shoulders and thorax were covered with dried blood. The pulse was very feeble and rapid—120. The patient had been seen by a medical man outside the hospital, who (as we subsequently discovered) had partially drawn together with sutures the wound in the trachea. The skin wound he had completely closed and had covered it over with cotton wool and collodion. There was spreading surgical emphysema extending from the neck to the costal margin, round to the back, and over the shoulders as far as the insertion of the deltoids. The supra-clavicular fossæ were filled out into prominent resonant swellings. The patient was very cold and covered with clammy sweat. The cotton wool and collodion were immediately removed and an incised wound about six inches long was exposed, extending across the front of the neck below the thyroid cartilage. The wound was double at the left extremity. The skin was held together by a continuous suture. The wound was opened up and a good deal of air at once escaped. The air made a hissing noise as it rushed in and out of an opening in the trachea. The left external jugular vein was bleeding; this was immediately ligatured. The patient was propped up in bed and an injection of ether and strychnia given. An enema of beef-tea and brandy was next administered. The patient soon rallied; cyanosis became less and the breathing slower. He still, however, complained of pain across his chest. Mr. Morris saw the patient soon after admission, but decided to wait till a few hours after the removal of the collodion and skin sutures with the hope that the patient would improve from the condition caused by the emphysema. At 6.30 P.M. Mr. Morris examined the wound, the patient being anæsthetised (ether). The sterno-hyoid and sterno-thyroid muscles on both sides were completely divided; the sternal portions had greatly retracted, leaving a wide gap between the divided extremities. The trachea was cut into just below the cricoid cartilage, and the membrane between it and the first ring of the trachea was divided from side to side. Another cut had shaved off the lower edge of the cricoid cartilage, and above this was a shallow wound of the thyroid cartilage which did not penetrate the larynx. Through the lowest wound air passed freely. A few bleeding points were now ligatured and all clot removed from the wound. The lower opening was first closed with fine silk sutures. The cartilage was very brittle and broke away several times from the needle and silk. The two other wounds were successively closed. There was now no further escape of air. The neck was then held well forward and the divided ends of the fascia and muscles approximated. These were sutured with fine silk. Some iodoform was dusted into the wound. The skin was then brought together with interrupted sutures, two small drainage-tubes were put in, and a dry boric dressing applied. The patient was sent back to the ward and his head and back supported on pillows. A binder was fixed round his waist and a cap with long strings prevented his head from straining backwards. After the operation the pulse was 110 and had much increased in volume. He was able to talk on recovering from the anæsthetic. He swallowed some milk the same evening. He passed a very comfortable night and on the following morning he could swallow liquid food quite easily. Expectoration was slightly blood-stained. He was put on bromide of potassium (10 gr.) three times a day on account of great mental restlessness. On April 12th emphysema was much less over the thorax, but had travelled over the abdominal wall and into the cellular tissue of the scrotum. A small trocar was introduced into the scrotum, which was enormously distended on the left side, and some air let out. The patient spoke clearly and swallowed liquids with comfort. The expectoration was muco-purulent and the cough rather troublesome. A suitable expectorant was given. On the 13th the dressings were changed and the tubes removed. The wound looked quite healthy. On the 15th the patient expressed his desire to get better. He now swallowed without pain, and had minced meat for dinner. The cough was less and the expectoration free from blood. The temperature was 100° F. in the evening and 99° in the morning. The pulse was 88. The dressings were disturbed from the patient's restlessness and had to be changed. The extremities of the wound had nearly healed. There was no tenderness at any point. The emphysema had almost disappeared from the abdominal wall and the scrotum, but did not clear up so rapidly about the thorax. There had, however, been no fresh emphysema since the closure of the wound by Mr. Morris. The back was quite free. By the 17th the wound had quite healed. There was distinct thickening of the cicatrix at its central part. The patient slept well and took plenty of food. On the 18th the stitches at the extremities of the wound were removed, and those in the centre on the 20th. The thickening in the centre of the scar formed a distinct ridge across the middle of the neck on a level with the cricoid cartilage. He was able to call in a loud voice, though somewhat muffled. There was a mere trace of emphysema below the clavicles and in the scrotum. The patient got up for the first time on the 22nd. He was discharged from the hospital on the 26th. All the emphysema had gone, the wound had nicely healed, and the voice had become much clearer. The ridge in the centre of the scar still persisted. The patient was seen on the 29th. The thickened tissue in the centre of the neck was being absorbed, and he expressed himself as feeling quite well.

Since this lecture was delivered I have had the gratification of reading Dr. J. E. Platt's paper on the Treatment of Wounds of the Air Passages.[4] Dr. Platt has had an exceptionally large number of these cases under his care during the two years he was resident surgical officer at the Manchester Royal Infirmary. I am very glad that success in the treatment of suicidal wounds of the throat by primary suture has led him to the same conclusions which I advanced in my earlier lectures and have repeated in this. If I judge correctly, Dr. Platt began the use of sutures in these cases with some misgiving as to their safety; but experience gave him confidence, and has convinced him of the security and other advantages of the treatment. I quite agree with him that a tracheotomy tube may in many cases be dispensed with, and that if a tube is used it should be introduced through a newly made vertical incision, and not through the suicidal wound in the air passages. I go much further than this, however, and say that I have not yet seen a case where a tracheotomy tube was required, and very much doubt if it is ever really needed. Indeed, I am persuaded that if employed it will delay the recovery and detract from the excellence of the result which will be obtained without it; and that more harm will be done by introducing it through the transverse wound of the suicide than through a vertical wound freshly made for the purpose by the surgeon. I do not attach the same importance to chloroform that Dr. Platt does. Ether has been given in some of my cases with equal safety. I think the old method of keeping the head bent towards the sternum during healing of great importance as a means of preventing tension on the sutures.

SOME PRACTICAL OBSERVATIONS UPON THE BACTERIOLOGY AND TREATMENT OF CATARRHAL OPHTHALMIA.

BY SYDNEY STEPHENSON, M.B. EDIN.,
OPHTHALMIC SURGEON TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN; SURGEON TO THE OPHTHALMIC SCHOOL, HANWELL.

ACUTE catarrhal ophthalmia, or muco-purulent conjunctivitis, is one of the commonest eye diseases met with in this country. Its contagiousness and epidemic tendency endow it with considerable practical importance, especially to those in charge of schools or similar institutions. Its symptoms no less than its treatment are known to every practitioner of medicine; there are, nevertheless, points in both that will repay further study. The object of the present paper (which is based upon a somewhat large experience of the malady) is to describe (1) the bacteriological diagnosis of catarrhal ophthalmia, and (2) those modes of treatment which I have found of most service. In the light of modern advances catarrhal ophthalmia must be regarded as due to a specific micro-organism. This fact was first pointed out by Koch, who, during a visit to Egypt in 1883, examined bacteriologically some fifty cases of the ophthalmia of that country. He found two microbes in the eye discharges—the one associated with severe, the other with mild, symptoms of disease. The former appeared to be identical with Neisser's gonococcus, while the latter he described as a very small bacillus. Haensell spoke in 1896 of having found an organism in catarrhal ophthalmia. In the same year John E. Weeks, of New York, published a careful memoir upon the subject. He discovered that small, well-defined bacilli were always present in the secretion of catarrhal ophthalmia. Inoculation of the eyes of rabbits and guinea pigs with the discharge gave negative results, but Weeks succeeded in setting up the disease when the specific pus was implanted on the human conjunctiva. He failed to obtain a pure culture of the organism, as he found a small, club-shaped bacillus in all his cultures. In six instances inoculation with the mixed growth gave rise to acute inflammation of the conjunctiva; the clubbed bacillus was found to possess no pathogenic properties. In 1887 Kartulis described the same orlganism in cases of Egyptian ophthalmia. Out of six inoculations of the human eye, Kartulis set up the disease twice. Morax (1894) concluded from his observations that the small bacillus was constantly present in this form of ophthalmia. Although inoculation of a pure culture failed to produce any result in animals, yet it succeeded upon his own eye. Somewhat later H. E. Juler mentioned the fact that he had met with the same organism in many, but not in all cases of catarrhal ophthalmia. But apparently he had not attempted to cultivate it. Weeks has recently reviewed the state of our knowledge concerning this microbe (1895). "Since the first observation of the micro-organism," he says, "the writer has examined between one and two thousand cases of acute contagious conjunctivitis, and has made many microscopical examinations of the secretion. Of the cases examined, the bacillus before mentioned was found to be a constant factor in the secretion." During the course of last year Morax and Beach published a full account of their experiments with this bacillus, which they managed to cultivate upon agar-agar, with or without the addition of

Hosted by Google

human blood serum. These authors express the definite opinion that acute catarrhal ophthalmia "invariably coincides with the presence of a small specific bacillus." For some years past I have made a point of examining bacteriologically the secretion from all doubtful cases of catarrhal ophthalmia that have fallen under my notice, and can fully confirm the observations of Weeks, Morax, and Beach. As stated in a work published a short time ago,[1] I am persuaded in my own mind that the presence of certain slender bacilli may be taken as diagnostic of this form of conjunctivitis, and, further, that the number of organisms present is directly proportionate to the severity of the case. Further experience has strengthened these views, so that I have come to regard a microscopic examination of the discharge from any inflamed conjunctiva as essential to a satisfactory and scientific diagnosis.

In a case where the surgeon suspects catarrhal ophthalmia, a first step is to make preparations from the stringy secretion present in the conjunctival sinuses. This is best done by everting the lids and removing a particle of discharge by means of a platinum loop, previously heated to redness and then allowed to cool. Two perfectly clean cover-glasses are next smeared with the pus, allowed to dry, and passed slowly two or three times over the flame of a spirit lamp or a Bunsen burner. They are next floated for a couple of minutes upon a 15 per cent. solution of acetic acid, thoroughly washed, dried, and once more heated. One of the cover-glass preparations is then stained with either Löffler's alkaline or with Kühne's carbolic methylene blue for five or ten minutes. The second, after immersion in absolute alcohol for two minutes, is treated by Gram's method, and counter-stained with a 0·5 per cent. solution of eosine. The specimens thus obtained are washed with distilled water, dried, mounted in Canada balsam and xylol, and examined microscopically with the aid of a 1 in 12 oil-immersion lens and Abbé condenser. If the case be one of catarrhal ophthalmia the preparation stained with methylene blue will be found to contain many polynucleated leucocytes and some epithelial cells in addition to the pathogenic microbes. The latter are short bacilli, varying in size from 0·75μ to 1μ. They resemble rather closely the bacilli of mouse septicæmia, but are smaller, and have rounded instead of angular ends. They occasionally form short chains by juxtaposition. They evince a special tendency to become grouped in the protoplasm of the pus cells, which in some preparations are literally loaded with them. Now and again the bacilli may be noticed to cling, as it were, to certain of the epithelial elements. Often enough, too, they may be seen lying free. They nearly always stain evenly; in the fresh organism I have never observed any signs of segmentation or sporulation. It is important to note that they become decolourised by Gram's method, so that in the second preparation one often enough fails to find a single microbe answering to their description. Intermixed with the organism of catarrhal ophthalmia the clubbed bacilli described by Weeks may be sometimes found. The two forms can be scarcely confused, inasmuch as the latter retains the stain in Gram's method. I incline to agree with Cuénod in thinking that these micro-parasites are identical with the so-called pseudo-diphtheritic bacilli, which are so often found in the mouth and upon the healthy conjunctiva. Their morphological appearances and staining and cultural reactions, at all events, are wholly consistent with such a view. In severe catarrhal ophthalmia the short bacilli occur in great numbers after the lapse of the first few hours. I have seen cases of this sort where scarcely a leucocyte in the specimen was free from one or more organisms. In mild types of disease, on the other hand, they may be so scanty that a careful search has to be made to find a single one, and, as everybody is aware who has examined for scattered microbes with high powers of the microscope, this process is likely to involve no small outlay both of time and trouble. Hence negative results possess merely a negative value, and do not altogether exclude the existence of slight or commencing catarrhal ophthalmia. The pathogenic organisms become progressively fewer and fewer with subsidence of the disease, but persist to some extent as long as discharge continues to be thrown off from the conjunctiva.

There are three types of acute inflammation of the conjunctiva in which I have found the short bacillus. These are: (1) classical catarrhal ophthalmia, the symptoms of which are so well known that they need not be described in this place; (2) a form associated with large phlyctenulæ in and about the conjunctiva—the "pustular" or "aphthous" disease of the older writers; and (3) a variety in which follicular enlargement is superadded to signs of acute inflammation. Once only have I found the micro-parasite under other circumstances—namely, in a child suffering from chronic dacryo-cystitis. Secretion pressed through the canaliculi into the conjunctival sinus contained numerous organisms of the kind. In relapses of catarrhal inflammation the bacilli are usually to be found in great numbers. It seems probable that in many instances these relapses simply mean re-infection brought about by the mingling of patients in various stages of the disorder. But in other cases we must assume that the organisms, incompletely subdued by treatment, have again obtained a mastery over the natural defences of the conjunctiva. All who have worked with the bacillus of catarrhal ophthalmia agree as to the difficulty of cultivating it. Weeks, after many experiments, came to the conclusion that it grew best upon 0 5 per cent. agar-agar at incubation temperature, an observation confirmed by subsequent writers. Speaking for myself, I have failed completely with potatoes, gelatin (10 per cent. and 20 per cent), and blood serum. I have succeeded but rarely with 1 per cent. to 2 per cent. agar-agar, but have been somewhat more fortunate with the medium recommended by Weeks, especially when glycerised. In my experience, however, the bacillus grows much better on serum-agar, prepared in accordance with the directions given in THE LANCET by Dr. A. A. Kanthack and Dr. J. W. W. Stephens.[2] In tubes of this material colonies of the specific bacillus may be generally observed within forty-eight hours after inoculation from a case of marked catarrhal ophthalmia. They are round, oval, or angular in contour, greyish-white, and so transparent that they may be readily overlooked. When magnified they are found to have a dew-like appearance, more easily recognised than described. The colonies remain discrete for many days; even after long growth they seldom exceed 0·5 mm in diameter. It is to be noted that the organisms soon lose their vitality, so that it is usually a difficult matter to transplant them after the lapse of three or four days. Under such circumstances, moreover, they stain imperfectly and show signs of involution and degeneration. It is, perhaps, fortunate that cultivation is by no means essential to diagnosis. The staining of cover-glass preparations made from the eye discharges is sufficient for all clinical purposes.

The state of our knowledge as to the organism of catarrhal ophthalmia appears to me to permit of the following conclusions being drawn: (1) the bacilli are to be found at some stage in every case of catarrhal conjunctivitis, and constitute the only certain diagnostic of that disease; (2) their numbers stand in direct relationship to the severity of the symptoms; and (3) they are difficult to grow upon artificial media and are readily killed by antiseptics, drying, or perhaps by mere lapse of time. A clinical distinction is often drawn between a muco-purulent (or yellowish-white) and a purulent (or yellow) discharge from the conjunctiva. This difference possesses some practical importance from a diagnostic standpoint. It is, however, mainly quantitative, and depends upon the relative proportion of migrated leucocytes. The characters of the exudation must obviously be the resultant of two factors: (*a*) the strength of the excitant, whether mechanical, chemical, or septic; and (*b*) the reaction of the conjunctiva to that stimulant. While it is broadly true that catarrhal ophthalmia is associated with a yellowish-white and the purulent disease with a yellow discharge, yet exceptions to this general rule are by no means uncommon.[3] This element of confusion probably accounts for the views of some writers, who appear to think that the contagious ophthalmiæ form a series of closely related and interchangeable disorders, ranging from the muco-purulent to the purulent type. As a matter of fact, the diagnosis of every case should be based, not upon the naked-eye characters of the secretion, but upon the organisms contained in that fluid. Thus, if gonococci be present we are dealing with a

[1] Epidemic Ophthalmia, its Symptoms, Diagnosis, and Management, 1895, p. 20. Young J. Pentland, London and Edinburgh.

[2] THE LANCET, Jan. 25th, 1896, p. 231.

[3] The manifestations of catarrhal, like those of other forms of ophthalmia, vary somewhat according to the age of the patient. For example, in children discharge, and in adults conjunctival redness, is the most striking sign; corneal complications, although exceedingly rare in the first, are less uncommon in the second class. The specific bacillus, however, can be found in all cases, so that the clinical differences are probably due to variations in structure or function of the parts concerned.

Hosted by Google

specific purulent ophthalmia, whereas if the bacilli described above be found we have to do with a specific muco-purulent, or catarrhal, ophthalmia. In other words, these affections of the conjunctiva are of a specific nature, and no more tend to pass into one another than scarlet fever tends to merge into German measles, or typhoid fever into diphtheria. Indeed, the time has come when the old designations might be replaced by others more in keeping with the present state of knowledge. We might now fitly speak of conjunctival inflammations as due to gonococci, to trachoma-cocci, to Weeks bacilli, to streptococci, to Klebs-Löffler bacilli, or to pneumococci—to name some of the forms only that can be identified with more or less approach to certainty.

With regard to treatment, the experience of some hundreds of cases has convinced me that nitrate of silver is the sovereign remedy for catarrhal ophthalmia. Under its influence redness and discharge subside, œdema of the lids is reduced, and the patient's discomfort is speedily abated. The acuter symptoms seldom withstand more than three or four applications. Whenever the diagnosis is assured the sooner silver is resorted to the better. In the mildest forms of disease only can we afford to dispense with it: the severer the type the more fearlessly may it be applied. The 2 per cent. solution in general use can hardly be improved upon. It is far more efficient than the 0·5 per cent. or the 1 per cent. liquid, and causes no more discomfort. It should be brushed over the everted conjunctiva, which has been first carefully freed from secretion. So far as possible its action should be limited to the mucous lining of the lids by attention to the two following points: first, the brush should be barely moistened with the lotion; secondly, any surplus silver should be soaked up from the conjunctiva by a swab of absorbent wool damped with weak corrosive sublimate. Neglect of these precautions will be likely to entail damage to the mucous membrane, and thus interfere with the regular application of our most potent remedy. According to my experience, silver is not contraindicated by corneal complications, as, for example, the small peripheral ulcers occasionally met with, especially in adults. Under no circumstances, however, should it be applied when raw or bleeding spots are present about the conjunctiva, for if that were done not only would needless pain be caused, but cicatrices also would probably result. The discomforts inseparable from a treatment applied at night are avoided at the Hanwell Ophthalmic School by using the silver in the early morning.

The following observations appear to throw some light upon the *modus operandi* of lunar caustic. A cover-glass preparation from a case of acute catarrhal ophthalmia, as already explained, will be found to contain pathogenic bacilli and polynucleated leucocytes along with epithelial cells. Now let preparations be made from such a case four, eight, thirteen, sixteen, twenty, and twenty-four hours after a 2 per cent. solution of silver nitrate has been brushed over the conjunctiva. Organisms, although plentiful before the application, will be almost or altogether absent from specimens obtained during the next twelve hours; but there will be a notable increase in the number of epithelial cells and fibrin filaments. Even sixteen hours afterwards the bacilli are few and far between and stain imperfectly. As a rule, however, after the lapse of twenty hours, there will be no great difficulty in finding them in most parts of the preparation. If the case be now left without treatment they soon multiply, so that within forty hours after silver was used almost as many will be present as in the original specimen. The same sort of thing may be shown in a different way. It has been already stated that there is considerable difficulty in growing the organism of catarrhal ophthalmia, but the difficulty becomes an impossibility if tubes be inoculated at any time within twenty hours after the employment of silver. From these facts we conclude that this agent acts by direct destruction of microbes. It is of practical interest to note that the latter in my experience are always confined to the surface layers of the conjunctiva. Silver should be continued until (*a*) swelling and redness of the palpebral conjunctiva have subsided, and (*b*) yellowish-white discharge has yielded to a scanty morning secretion containing no bacilli. From five to fifteen brushings are generally needed to attain these ends. The uneasy sensations associated with catarrhal ophthalmia are mainly due to the accumulated discharges, which act partly as a mechanical and partly as a septic irritant to the conjunctiva. Hence constant removal of secretion is almost as necessary to a speedy cure as it is grateful to the patient. As a wash for general use nothing succeeds better than one-eighth of a grain of corrosive sublimate in an ounce of water, with the addition of one grain of ammonium chloride. The latter increases the solubility of the mercuric salt and prevents the formation of an albuminate when the lotion comes into contact with the conjunctiva. This collyrium, previously warmed, may be used from three to eight times a day, and in order that discharge may be thoroughly removed the mucous membrane should be freely exposed by everting the eyelids. Furthermore, it is always well in catarrhal ophthalmia to prevent any adhesion of the lids by means of a little lanolin or other simple ointment introduced into the eyes at bedtime. When the acuter symptoms have subsided silver is to be replaced by some less stimulating eye-wash, such as 2 grains of lapis divinus and 30 minims of laudanum to the ounce of distilled water. Sulphate of zinc or alum lotion (from 1 to 3 grains to the ounce) succeeds well in some instances. I have obtained the most satisfactory results, however, from the old-fashioned yellow lotion of the Austrian Pharmacopœia, which is thus prepared: ammonium chloride 0·5 part, and zinc sulphate 1·25 parts, dissolved in 200 parts of distilled water. Next camphor 0·4 part is dissolved in 20 parts of absolute alcohol, and 0·1 part of saffron added to it. The two solutions are then mixed, allowed to stand overnight, and filtered. The undiluted lotion should be dropped over the everted eyelids twice or thrice a day. It generally gives rise to some smarting when first used, but the patient soon grows accustomed to it. My experiences with formal (1 to 2000) have, upon the whole, been disappointing. It often causes much pain, may excoriate the conjunctiva, and, to my thinking, is inferior in every way to the remedies enumerated above. In a few cases oleaginous preparations seem to suit better than watery solutions, in which event the choice will lie between the yellow oxide and ammoniated mercury. A 2 per cent. to 4 per cent. ointment of either salt is prepared with equal parts of lanoline and vaseline and used twice a day. Whichever be selected it is important that the remedy be brought into close contact with the conjunctiva, and this is best done by manipulation of the eyelids, or "massage," as it is called. The treatment of every case should be commenced by the administration of a brisk purge, after which a daily evacuation of the bowels should be secured by one or other of the methods in general use. Bandages should be employed exceptionally only. But it goes almost without saying that those with acute catarrhal ophthalmia must shade the eyes from light. They should avoid reading or other close work, live temperately, and spend as much time as possible in the open air. Under proper treatment catarrhal ophthalmia recovers speedily and completely—that is to say, not only does discharge cease, but the palpebral conjunctiva returns to its normal condition. Neglected cases, however, may drag on for months. During the whole of this time more or less secretion continues to be thrown off from the mucous lining of the lids, and since this contains the specific organism, such patients may be a fruitful source of infection to all around. It is therefore of the utmost importance that cases be taken in hand early and that treatment be persevered with until cure is complete. In conclusion, let me earnestly insist upon the inadvisability of allowing patients with catarrhal ophthalmia to be associated in the same wards with those affected with the purulent disease or with trachoma.

Those interested in catarrhal ophthalmia are recommended to consult the following among other recent publications: Koch: *Wiener Medicinische Wochenschrift*, 1883, No. 52; Weeks: *Archives of Ophthalmology*, 1886, p. 441; also Verhandlungen des Internationel Medicinischen Congresses, Berlin, 1890, Band iv., p. 38; also *New York Eye and Ear Infirmary Reports*, January, 1895, p. 24; Juler: *Brit. Med. Jour*, Sept. 15th, 1894; Cuènod: *Gazette des Hôpitaux*, 1894, p. 989; Morax: *Recherches Bacteriologiques sur l'Etiologie des Conjonctivites Aiguës*, 1894; Morax and Beach: *Archives of Ophthalmology*, January, 1896, p. 54.

DEATHS AFTER OVARIOTOMY, WITH REMARKS ON THE VALUE OF FLUSHING WITHOUT SUBSEQUENT DRAINAGE OF THE PERITONEAL CAVITY.

BY W. A. MEREDITH, M.B. EDIN., F.R.C.S. ENG.,
SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL.

IN October, 1888, I read before the Royal Medical and Chirurgical Society a paper on the "Mortality of Abdominal Section," founded chiefly upon the results of a first series of 100 ovariotomies, of which number 10 had proved fatal.[1] In February of the present year I completed a further series of 250 operations for the removal of ovarian tumours, with 243 recoveries and but 7 deaths — a mortality of 2·8 per cent. The following details of these 7 fatal cases appear to me to be worth recording as illustrative of some of the risks and complications liable to be encountered in dealing with ovarian growths; and I venture to hope that this relation of my failures may prove of some use to others who are working in the same field as myself.

CASE 1 (145).[2]—A woman, aged fifty-six years, the mother of four children, was sent to me at the Samaritan Hospital in October, 1890, by Dr. Livingston, of Hursley. The menopause had occurred seven years before, and during this interval she had once seen a return of coloured discharge five years previously to her admission. She was greatly emaciated and both lower limbs were very œdematous; the abdomen was enormously distended by a cystic tumour displacing forwards the xiphoid cartilage, and expanding the costal arch on each side. On Oct. 24th double ovariotomy was performed. The left tumour—a practically unilocular cyst—was completely sessile, necessitating for its removal a very extensive and troublesome enucleation; the resulting rent in the left broad ligament was subsequently closed by a series of six deeply-placed interlocking ligatures for the arrest of hæmorrhage, and the peritoneal edges were then accurately united by a continuous suture of fine silk. The right tumour, consisting of a thick-walled very multilocular growth with a good deal of semi-solid material, was unadherent, and its removal entailed no difficulty. The abdomen was closed without flushing or drainage, the relaxed parietes being carefully supported by strapping and a flannel binder applied over the usual dressings augmented by a large mass of cotton wool. The aggregate weight of the tumours exceeded 50 lb. (42 pints of fluid and nearly 9 lb. of solid material). Convalescence during the first week was quite uneventful, the highest recorded temperature being 99·8° F., with a pulse-rate of 76; the bowels acted naturally from the third day onwards; and the dressings were changed on the sixth day, when the incision was found to be well united, and the sutures were consequently removed, the abdomen being subsequently carefully restrapped and supported as before by a binder. During the next forty-eight hours progress continued to be satisfactory, and on the evening of the eighth day the patient was left in excellent spirits, with a perfectly normal temperature and pulse, without cough or discomfort of any kind, and apparently well advanced on the road to complete recovery. The weather at the time was exceedingly wintry, with a biting east wind and very low temperature, and during the night she must in some way have been exposed to chill, for at my visit next morning I found her condition totally altered. She was lying propped up in bed complaining of severe dyspnœa and of pain in the left side of chest, examination of which revealed some deficiency of resonance over the base of the lung with much coarse crepitation; the left upper lobe and the right lung throughout were resonant, but the breath sounds were much obscured by râles. The abdomen was quite soft and natural, the bowels having acted without help during the early morning; per vaginam the uterus was found freely mobile, and no tenderness or fulness was detected in the pelvis. The temperature and the pulse, which were 98·4° and 72 respectively on the previous evening, had risen to 102·2° and 116 respectively; the respirations were 36, and there were no sputa, although cough was constant. During the next twenty-four hours the temperature rose gradually to 104°, with a very feeble, intermittent pulse, and a moderate amount of thin, frothy, muco-purulent secretion was brought up, but expectoration was evidently much impeded by the relaxed state of the diaphragm and abdominal muscles. The patient rapidly lost ground in spite of very free stimulation, the breathing becoming more and more laboured and the heart's action more enfeebled as the lung secretion accumulated, until death took place on the morning of the twelfth day, seventy-two hours subsequently to the onset of the lung mischief. I was unable to obtain a post-mortem examination, but there could not under the circumstances be any doubt as to the cause of death.

This unfortunate termination to a promising case was very disappointing, although on reviewing it I cannot see how recovery from such a condition could well be hoped for. The lesson to be learned from it points to the advisability, when dealing with large, old-standing ovarian cysts which exert much upward pressure on the diaphragm, of removing a portion of their fluid contents by aspiration a few days before the major operation is undertaken; by so doing one may promote the gradual expansion of the compressed lower pulmonary lobes, and thus place the patient in a better condition for withstanding the shock of a severe operation and for subsequently resisting the onset of any lung complication should such arise.

CASE 2 (212).—A single woman, fifty-eight years of age, of feeble physique and extremely emaciated, was admitted into the hospital in April, 1893. The menopause had occurred five years before, and she had known of the existence of an abdominal tumour for about a year. Four months previously to admission she had suffered from a sudden attack of abdominal pain, which confined her to bed for seven weeks. On examination the abdomen was found to contain an extremely tender, elastic tumour extending upwards on the left side to the level of the costal arch, and apparently fixed by adhesions. The history suggested a twisted pedicle. The patient was operated upon on April 25th. The tumour proved to be an ovarian cyst covered by coils of adherent intestine and connected below with the right side of a normal uterus by a very tightly twisted pedicle showing three distinct turns. The cyst wall was very rotten, of a dark-greenish hue over its upper portion, and dark purple in colour towards the base, where it was extensively adherent in the pelvis; the contained fluid measured 9 pints. The pedicle was transfixed and tied well below the lowest twist, and before closure the abdominal cavity was flushed out and a drainage-tube inserted. The operation, performed at 9.30 A.M., lasted just over one hour, and the patient soon regained consciousness. During the first twelve hours the condition was fairly satisfactory, the temperature rising slowly to 100° F., with a somewhat feeble pulse of 110. At 9 P.M. the tube dressings were changed, about ½ oz. of blood-stained fluid being withdrawn; at the same time 3 oz. of urine were obtained by the catheter, of low specific gravity and containing a small amount of albumin, of which no trace had been discovered before operation. Shortly after this the patient became restless and the temperature rose to 102°, with a very rapid intermitting pulse; no more urine was secreted and she gradually became insensible, dying quietly at 4 A.M., about seventeen hours after the removal of the tumour.

The post-mortem examination revealed nothing amiss in the peritoneal cavity; both kidneys were contracted and granular with very adherent capsules; the heart, weighing 9½ oz., was laden with fat and its substance was soft and flabby, the cavities were distended, and the valves normal. The cause of death was attributed to shock consequent on cardiac and renal disease of old standing.

CASE 3 (250).—A very feeble and emaciated woman, aged sixty-six years, was first seen in October, 1894, in consultation with Dr. Uhthoff, of Brighton. The menopause had occurred at the age of fifty-one years, but for ten years previously to the date of my visit she had been subject to occasional slight uterine hæmorrhages, although her general health had continued fairly good until about twelve months before (October, 1893), when she began to lose flesh rapidly and the abdomen enlarged. In May, 1894, she consulted Dr. Uhthoff, who tapped her, removing 25 pints of (?) free fluid. This operation was repeated in the following July, when 12½ pints were taken away. At my examination three months later I found a considerable quantity of

[1] Transactions of the Royal Medical and Chirurgical Society for 1889, vol. lxxii.

[2] The figures in parentheses refer to the total number of ovariotomies performed.

Hosted by Google

peritoneal fluid surrounding an elastic tumour, of which the base entirely filled the pelvic cavity, displacing upwards a bulky uterus, which was easily recognisable above the pubes in close connexion with the anterior surface of the tumour. The bowels were evidently much loaded; the urine was scanty, highly coloured, and of specific gravity 1016; there was no albumin. My diagnosis was ovarian tumour, possibly malignant, with ascites, and I advised exploration. The operation was performed on Oct. 20th, 1894. The growth proved to be a semi-solid ovarian tumour composed mainly of brain-like material of extremely soft consistence and very suggestive of malignancy.[3] Adhesions were very extensive, especially in the pelvis, where a broad vascular pedicle was connected with the right side of the uterus. The left Fallopian tube was distended to the size of a large sausage (hydrosalpinx). I tapped, but did not remove it, as the corresponding ovary was quite atrophied. Finally, the abdominal cavity was well flushed and closed without drainage. The weight of the tumour, apart from the ascitic fluid, amounted to between 9 lb. and 10 lb. During the first five days progress was uneventful, with a temperature not exceeding 99·2° F., and a pulse-rate varying between 90 and 100; nourishment was well taken, the kidneys acted freely, and the abdominal condition remained satisfactory; the only trouble complained of was want of sleep. On the morning of the fifth day the bowels acted with the help of an enema, dark liquid motions with numerous small scybala, and these recurred at frequent intervals throughout the day, accompanied by the escape of large quantities of extremely offensive flatus. The patient complained for the first time of very severe headache, with a general sense of depression, and towards evening she was inclined to wander. This mental condition became aggravated during the night; she grew very restless, requiring some control to prevent her from getting out of bed, and constantly complaining of the pain in her head; there was no sickness, and she took plenty of liquid nourishment; the temperature touched 100° for the first time since the operation, with a pulse of 108. When seen in the morning of the sixth day she appeared so worn out by want of sleep that I administered one-third of a grain of morphia hypodermically. Shortly after that she fell asleep, and remained so throughout the afternoon, breathing very deeply and irregularly at the rate of only 12 respirations per minute; the face was very flushed, the eyelids were only partially closed, and the pupils moderately contracted; the temperature varied between 99·8° and 100°, with a pulse-rate of from 72 to 96. She took nourishment readily without fully awaking and passed urine at rather frequent intervals. At 9.30 P.M., after she had remained in this condition for between eight and nine hours, I roused her without any difficulty, but found her quite as excitable and wandering as before her sleep. She still complained greatly of headache, and was extremely restless until after the bowels had again acted at 11.30 P.M., when she grew quieter, the temperature meantime having risen to 101°, with a pulse of 116. She gradually passed into a comatose condition, and so remained until her death at 5 P.M. on the following day, which was preceded by two distinct convulsive seizures, each one lasting for about a minute.

• I was unable to obtain leave for an examination, and therefore cannot be certain as to the cause of death, but judging by the onset and development of the fatal symptoms I am inclined to attribute them to toxic poisoning from intestinal absorption in an aged and very feeble subject with unhealthy kidneys. The advisability of giving morphia in such a case is more than doubtful, and I certainly should not again resort to it under similar circumstances, although I hardly think that in the present instance its administration materially influenced the result.

CASE 4 (275).—A woman, aged seventy years, was first seen in consultation with Dr. Gray, of Oxford, and Mr. Garnham, of Herne-hill, in January, 1895. The abdomen contained a very mobile ovarian cyst of moderate size, and I advised early operation in view of the likelihood of the pedicle becoming twisted. Shortly after my visit the patient was laid up by a sharp attack of influenza, subsequently complicated by bronchitis, and operative treatment was consequently postponed for some months. I did not again see her till the following June, when the cyst appeared to me to be less freely moveable and decidedly more tender than before, but I failed to obtain any definite history pointing to rotation of the pedicle. On June 7th, 1895, the operation was performed. The tumour proved to be a left ovarian cyst, from 7 to 8 lb. in weight, with a very tightly twisted pedicle and universal adhesions. Its removal was a very troublesome business, necessitating the application of numerous ligatures to omental, intestinal, and mesenteric connexions. The abdominal cavity was freely flushed out at the conclusion of the operation and closed without drainage. During the first five days all went on well. The temperature once touched 100·6° with a pulse of 88 in the evening of the second day, but fell to normal in the course of the next twelve hours and did not rise again. Nourishment was well taken after the first twenty-four hours, and the abdomen remained free from distension or tenderness; the kidneys acted abundantly from the first. At 2 A.M. on the sixth day after the operation the patient woke up suddenly complaining of stomach ache, and shortly afterwards vomited some coffee-ground fluid; an hour later a small dark blood-clot was passed per anum, which was presumed to proceed from hæmorrhoids, and a soap-and-water enema, administered to promote an action of the bowel, returned almost immediately mixed with a quantity of dark fluid blood without trace of fæces. I was at once sent for, and on arriving at 5 A.M. found the patient looking pale and anxious and inclined to be somewhat restless, although quite free from pain; the abdomen was soft and not notably tender anywhere on pressure, and normally resonant, without a trace of distension; the temperature was 97·8°, with a compressible pulse of 84. Nothing was to be felt per rectum, and I came to the conclusion that the hæmorrhage must proceed from a stercoral ulcer. At 6 A.M. a further considerable quantity of dark fluid blood was voided per anum, and this same recurred at 7.30 A.M., shortly before which hour some coffee-ground fluid was again vomited. The temperature had now fallen to 97°, while the pulse had risen to 120. No more blood was passed until 9.15 A.M., when a further very copious discharge took place, after which the patient rapidly collapsed and died quietly at 9.45 A.M., within eight hours of the first manifestation of her condition. The post-mortem examination, made by Dr. Allchin, revealed no trace of peritonitis; the pelvic cavity contained two ounces of blood-stained fluid. All the tissues were markedly exsanguine. The liver, spleen, and pancreas were fairly normal, but both kidneys were small, and on section showed a very advanced condition of interstitial nephritis. The lungs were healthy, but the heart was enlarged and loaded with fat. The intestinal canal throughout showed deep purple staining of the mucosa, which was otherwise normal until within one and a half inches of the pylorus, where an irregular-shaped ulcer was discovered, evidently on the verge of perforation, and adhering to its floor was seen a small, recent blood-clot seated in close proximity to what appeared to be an ulcerated vessel. To quote Dr. Allchin's report: "I have no doubt from the general appearances that the hæmorrhage occurred from this site. The duodenal ulcer was an old one—i.e., of several years' standing. Death is amply accounted for by the hæmorrhage, which must have been very considerable, as the bloodvessels generally were quite empty. The condition of the kidneys, however, was such that I much doubt whether the patient could in any event have recovered."

This case is, I believe, unique in the annals of ovariotomy, so far as regards the cause of death. The absence of any premonitory symptoms whence the existence of a duodenal ulcer might have been deduced rendered it impossible to accurately locate the source of the hæmorrhage when the patient was first seen on the morning of her death; and although it seemed clear enough at the time that the bleeding must proceed from a stercoral ulcer I pictured this as probably situated in the large bowel. Under the circumstances, however, no operative treatment could have possibly saved her, even though undertaken with accurate knowledge as to the seat of the bowel lesion.

CASE 5 (304).—The patient, a young woman, nineteen years of age, first seen in consultation on March 17th, 1896, had apparently enjoyed good health until five days before, when, coincidently with the onset of the monthly period, she was suddenly seized with very severe abdominal pain, accompanied by vomiting and fever. On examination under an anæsthetic I found the abdomen occupied by a tense elastic swelling, rising to just above the level of the umbilicus and filling the pelvic cavity below in front of a small uterus, which was displaced backwards into the right posterior

[3] The specimen, reserved for microscopical examination, was unfortunately thrown away.

Hosted by Google

quarter of the space. I considered the tumour to be ovarian, probably with a recently twisted pedicle; but as menstruation was persisting very freely at the time it was decided to postpone interference for a few days. During the course of the next forty-eight hours the flow gradually lessened and both pain and sickness were much relieved; the temperature, from 101° F., subsided to 99·6°, and the pulse, which had been extremely feeble and rapid, slowed down to about 100. Operation was performed at 11 A.M. on March 22nd. On exposure the cyst wall appeared of a deep plum colour. After separation of extensive recent parietal, omental, and pelvic adhesions the tumour was tapped and four pints of ordinary ovarian fluid, but slightly blood-stained, were withdrawn, and the flaccid sac which, although very soft and friable, was tolerably thick-walled, was then extracted whole without difficulty. The pedicle connected with the right side of a normal uterus was unusually short and had rotated one full half turn from left to right; it was secured by transfixion below the twisted portion previously to division. The peritoneal cavity was then flushed and closed without drainage. I saw the patient again at 6 P.M., when her condition appeared to be quite satisfactory; the temperature was 99 8° and the pulse 108; the skin was moist; there were no sickness and no unusual amount of pain; the kidneys had acted freely, and she expressed herself as feeling much more comfortable than she had expected. I heard nothing more until eight o'clock the next morning, when a telegram reached me stating that she had died at 6 A.M. On inquiry I learned that in the course of the previous evening she became somewhat restless, the temperature rising to 102°, with a pulse of 120; but her condition apparently gave no cause for alarm when she was visited by her medical attendant at 10 P.M., as there were no other unpleasant symptoms of any kind. During the next five hours, however, the restlessness increased, as the temperature gradually mounted to 103°; by 4 A.M. it had reached 104°, and the stage of excitement had passed on to actual delirium. At 4.45 A.M. a dose of morphia was administered hypodermically, and this was repeated half an hour later. Shortly after the second dose the patient became comatose and died quietly at 6 A.M., with an ante-mortem temperature of 105 4°.

As no examination was permitted one cannot feel certain as to the cause of death; but on reviewing my notes I am inclined to attribute it to hyperpyrexia induced by shock in an extremely nervous and excitable patient. The administration of morphia under the circumstances was a mistake. The proper treatment would have been to reduce the temperature at any cost, and this should have been effected by the continuous application of ice to the head, combined with cold wet packing of the extremities.

CASE 6 (314).—A married woman, aged forty-eight years, anxious-looking, spare, and very anæmic, the subject of a moderate-sized goitre, was admitted into hospital under my care at the request of Dr. Raby, of Devizes, in May, 1896. Eight years previously to her admission she noticed a small lump situated in the left iliac fossa, which was diagnosed as a uterine fibroid. The tumour grew very slowly until about nine months before I saw her, when it suddenly took on rapid increase. She was extremely emaciated, and stated that she had persistently lost flesh ever since a severe attack of diphtheria five years before. The menopause dated three years back. The urine was somewhat scanty and of low specific gravity (1015); no albumin was discoverable. The abdomen was filled by a tense cystic tumour rising to the level of the costal arch and extending deeply in the pelvis, whence the uterus was displaced upwards into the abdominal cavity, being there recognisable in close connexion with the front of the tumour somewhat to the left of the middle line. Operation was performed on May 28th, 1896. The tumour proved to be a double fused ovarian cyst containing fourteen pints of fluid laden with cholesterine. Its upper portion was unadherent, but below the level of the umbilicus its relations became very complicated; in the middle line the cyst wall was intimately connected with the posterior surface of the displaced uterus, whence the growth burrowed deeply on either side between the layers of the broad ligaments, being overlaid by the Fallopian tubes, both of which were greatly hypertrophied. The deeper portions of the tumour were very firmly embedded on the left side beneath the sigmoid flexure and upper two-thirds of the rectum, and on the right beneath and behind the cæcum, whence the vermiform appendix, thickened to the size of one's little finger, and elongated to the extent of seven or eight inches, overlay the growth, and was firmly adherent to the fundus uteri. The enucleation of these deeper portions was an exceedingly difficult and tedious business, owing to the toughness of the attachment and the close connexion with bowel on both sides; but it was at last satisfactorily accomplished. The very firm adhesion to the back of the uterus was cautiously severed by means of scissors, and finally both ovarian pedicles were ligatured and divided. The numerous pressure forceps were then removed, and the peritoneal cavity having been very freely flushed out was closed without drainage. The operation lasted two and a half hours. The patient soon recovered consciousness; the temperature, which was 98·2° F. when she was placed in bed, rose to 100·8° in the course of the next few hours, with a pulse of 120, about the same rate as before the operation. During the next twenty-four hours the temperature ranged between 100° and 101°, but the pulse beats mounted to 140; there was no sickness, and flatus escaped very freely, so much so as to interfere with the retention of nutrient enemata; the kidneys acted abundantly. On the second day the average temperature was somewhat lower, but the pulse rate increased, varying between 144 and 160; the bowels acted freely several times, and the rectal injections were subsequently better retained. During the night the patient had a few hours' sleep for the first time since the operation, and awoke somewhat refreshed, but there was no material alteration in her condition during the third day, excepting that she showed aversion to taking nourishment, which during the previous forty-eight hours she had accepted readily. Early in the morning of the fourth day she became very restless and excitable, although she had slept at intervals during the night; the temperature, which in the previous day had fallen to below 100°, rose to 102°, with a pulse of 140; the bowels acted freely with a soap-and-water enema, which was repeated in the course of the day. Her mental condition, however, continued very unsatisfactory, alternating between semi-maniacal attacks, during which she required restraint, and complete lapses of consciousness lasting for an hour or two hours at a time. She obstinately refused to swallow any nourishment, and voluntarily expelled the nutrient enemata and suppositories, the administration of which was rendered extremely difficult by her violence. After lingering on in this hopeless state for seventy-two hours she died practically from starvation early on the morning of the eighth day after the operation, no nourishment of any kind having been swallowed or retained during the last four days of life.

The following report of the post-mortem examination was furnished to me by Dr. Allchin. "Rigor mortis well marked; body extremely emaciated; no attempt at union of the incision; abdominal cavity perfectly dry, without trace of peritonitis anywhere; the hollow viscera were extremely retracted and there was a very notable absence of fat. All abdominal organs were healthy with exception of the kidneys, of which the right one was small and moderately contracted, while the left was converted into a mere sac owing to dilatation of pelvis and calyces, the renal substance being reduced to a thin shell barely a quarter of an inch in thickness; no actual obstruction of the left ureter was discovered, and it must therefore be presumed that the condition resulted from long-standing pressure (i.e., of the tumour in the left side of the pelvis)." The cause of death was entered as inanition, renal inadequacy being set down as a secondary factor.

This is the only fatal case of insanity which I have met with in my abdominal work. In but two other instances (one ovariotomy and one abdominal hysterectomy) have I seen well-marked mental trouble following upon the removal of large abdominal tumours, and both these patients recovered completely within a few months of the operation. The above three cases are the only ones met with in a series of over 700 abdominal sections, and in each instance the tumour had existed for many years before its removal—a fact worth noting with regard to prognosis under such circumstances. On the other hand, a slight degree of mental disturbance, usually characterised by moroseness, with occasional fits of irritability, is not an extremely uncommon feature of early convalescence after removal of large tumours in middle-aged women; this condition in my experience is a merely transitory one, most noticeable in patients who have long suffered from chronic constipation associated with the presence of slowly growing pelvic tumours.

CASE 7 (349).—A stout and very anæmic woman, aged forty years, the mother of one child twenty-two years old, was admitted into hospital in January, 1897, suffering from

Hosted by Google

pelvic pain of a sufficiently severe character to incapacitate her for work. She had been in failing health for some eighteen months, and had latterly begun to lose flesh. The heart-sounds were feeble, but no murmur was detected; the urine was scanty, highly coloured, and slightly turbid, of specific gravity 1025, and there was no albumin. The abdominal parietes were loaded with fat, excepting over the seat of a large, irregular, depressed cicatrix in the right hypochondrium, said to have been caused by the bursting of an internal abscess twenty years before. The left iliac region was occupied by a firm, tense swelling rising out of the pelvis to the level of the crest of the ilium, and extending just across the middle line. Per vaginam the base of the tumour filled the left half of the pelvic cavity, being evidently closely connected with the left side of a somewhat bulky uterus. The mass was diagnosed as an intra-ligamentous ovarian cyst. Operation was performed on Feb. 10th, 1897. The abdominal wall contained a most unusual amount of fat, and the subjacent omentum was adherent to the parietal peritoneum. The right ovary, cystic and enlarged to the size of a hen's egg, was buried in old adhesions at the bottom of the pelvis, and its removal entailed a good deal of difficulty; the Fallopian tube overlying it contained a mass of cretaceous material—presumably the remains of an old pyosalpinx. The tumour on the left side, of the size of an infant's head, proved to be a sessile ovarian cyst completely encapsuled between the layers of the broad ligament, and overlaid externally by the sigmoid flexure. Its enucleation was a troublesome business owing to the extreme toughness of its connexions and the depth to which it extended; the contained fluid was laden with cholesterin. The damage inflicted on the broad ligament during the removal of the growth precluded the possibility of successfully suturing the remains of the torn capsule. I therefore freely flushed out the abdominal cavity and closed it at once. For the first twenty-four hours after the operation the patient's condition seemed satisfactory, excepting for the fact of an extremely feeble circulation. During the second night her temperature rose slowly to 101·6° F., with a pulse of 114, and both remained at or about this level for the next twenty-four hours, during which there was no sickness, the flatus passed regularly, and the kidneys acted fairly well. On the morning of the third day it was noted that the pulse-rate had increased to between 130 and 140, the temperature meanwhile having risen to 102·4°; there was no inclination to vomit, but the flatus had ceased passing, and the urine, which had become scanty, contained albumin. Towards evening the abdomen became very distended at the upper part, more especially in the left hypochondrium; a turpentine enema, administered through a long tube passed without difficulty for some eight or nine inches up the bowel, was followed by a very free escape of flatus, which afforded much relief for a time; but the distension recurred during the night and a repetition of the enema on the following morning produced no such result, and was succeeded by the vomiting of some coffee-ground fluid. From this time the patient rapidly lost ground, the heart's action becoming more and more feeble, as the distension increased, until her death, which took place before the completion of the fourth day. Post-mortem examination revealed no trace of recent peritonitis, but the following state of things was discovered: the liver, spleen, stomach, and transverse colon were matted together by extremely tough, fibrous adhesions of very old standing, of such density as to prove inseparable except by the use of the knife; the liver and spleen were further firmly adherent to the diaphragm, and the former was also closely attached to the abdominal wall down to the level of the scar in the right hypochondrium; the omentum was firmly united to the underlying intestinal coils, which were matted together by old adhesions. Both kidneys were small and pale, with very adherent capsules. The heart was laden with fat and its substance was pale and fatty; the lungs were fairly healthy; all the tissues were extremely anæmic. The pelvic pouch contained two or three ounces of blood-stained fluid; both ovarian pedicles appeared healthy; the uterus was bulky and its cavity contained a submucous fibro-myoma of the size of a duck's egg. The state of the abdominal viscera here described was amply sufficient to account for the fatal result when viewed in connexion with the condition of the heart and kidneys. There can be little doubt but that the adhesions dated from the attack which led to the discharge of pus through the abdominal wall twenty years before my operation; and the fact of the patient's survival and enjoyment of comparative good health during so many subsequent years, in spite of the existence of such a complicated condition of the abdominal viscera, is by no means the least interesting feature of the case.

Remarks.—The fact of 243 recoveries in a series of 250 major operations is satisfactory, but the comparative ease or difficulty of the individual recoveries is also worth some consideration. In the investigation of this subject a careful examination has been made of the notebooks of the cases in question, each one of which contains a complete record of the axillary temperature taken every two hours during the first two days after operation, and subsequently every four hours until the end of the first week, when the entries become less frequent as convalescence progresses. For purposes of classification I have selected in each case the highest temperature noted during the patients' stay under my care, although such record in the great majority of instances has been reached on but one, or at most two, occasions during the first forty-eight hours after the operation. By this method I have arrived at the results given in the subjoined table, which shows, in addition, the number of cases where special means were adopted for cleansing the peritoneal cavity, consisting of drainage (D.), of flushing followed by drainage (F.D.), or finally of flushing with immediate closure of the abdominal incision (F.).[4] The grouping of the cases in consecutive series of 50 serves to indicate the gradual adoption of the last-named plan of treatment as a substitute for either of the two former methods. The classification of the temperature records is that given in the article on Temperature contained in the last edition of Quain's Dictionary of Medicine.

Two recoveries with high fever (i.e., exceeding 103° F.) complete the total of 243. One of these cases occurred in the first group and the other in the third; both were flushed and drained.

It will be seen that in 205 cases (84 per cent. of the total number of recoveries) the temperature never exceeded 100·5°F., which point may, I think, be taken as the limit for what should be considered as a normal convalescence after a major abdominal operation; of the remaining 38 cases, 36

[4] The term *flushing*, as used in this connexion, is preferable to the word *irrigation*, which, although correctly applicable in the case of ordinary surgical wounds, is not accurately descriptive of the process of washing out the peritoneal cavity.

Hosted by Google

recovered with a moderate amount of fever (not exceeding 101·5° in 24 instances); and in only 2 cases out of the total number of 243 recoveries was there a rise of temperature sufficient to constitute high fever.

Special means for cleansing the peritoneal cavity were adopted in 118 (over 48 per cent.) of the 243 successful cases in the following relative proportions: Drainage in 16 instances—about 1 in 15; flushing and drainage in 36 instances—about 1 in 7; and flushing in 66 instances—about 1 in 4. To the adoption of this last-named method of treatment in cases presenting extensive adhesions or other intra-peritoneal complications I am inclined in great measure to attribute the results obtained, not only as regards actual recovery, but also in respect to the comparative ease and shortness of convalescence, and I therefore think it worthy of brief consideration here.

The value of flushing as a convenient and efficient means of removing blood-clot or effused fluids from the peritoneal cavity has now been pretty generally recognised for some years past, the usual practice in this respect being, so far as I am aware, to subsequently remove as much as possible of the water thus introduced, and, further, to provide, by the insertion of a drainage-tube, for the escape of any remainder which might not be readily absorbed. That such absorption takes place very rapidly, however, during the first twenty-four hours after operation is amply evidenced by the comparatively small amount of fluid to be obtained through the tube in cases where a very considerable quantity has been left in the abdomen, and it was the observation of this fact that first led me to try the effect of leaving the closed peritoneal cavity filled with water in the expectation that the serous membrane would be able safely to dispose of this fluid, together with any remaining blood-clot or any other concrete substance which by solution might be rendered absorbable. The results following this treatment, which I first carried out in a case of ruptured colloid ovarian cyst with very extensive peritoneal infection in March, 1889, have fully answered my expectations. Of the 66 cases above mentioned in which the closed abdominal cavity was designedly left filled with water at the conclusion of the operation,[5] 16 recovered with a normal temperature—i.e., not exceeding 99·5°; 38 recovered with a sub-febrile temperature, varying between 99 5° and 100·5°; and 12 recovered with moderate fever, ranging in six instances between 100 5° and 101·5°, and in the remainder between 101·5° and 103°.

These results appear to me sufficient to warrant one in advocating a method of treatment which has certainly helped in promoting them, and I will therefore, in conclusion, briefly enumerate what I consider to be the advantages attainable by its adoption. 1. The enclosed water, while tending in some measure to arrest venous oozing by the hæmostatic action due to its temperature, further acts beneficially by preventing fresh formation of clot in the event of the temporary persistence of such oozing after closure of the abdomen. 2. By its solvent action on any concrete substances, such as blood-clot, colloid material, or lymph, which may have escaped removal during the process of washing out, it promotes their absorption and thus prevents the establishment of a nidus for the development of septic mischief. 3. In a similar manner, by dilution, it facilitates the absorption of any ovarian or other remaining fluids liable to provide a medium for the growth of micrococci. 4. Owing to the rapid absorption of fluid thus taking place from the peritoneal cavity during the forty-eight hours immediately succeeding operation the urinary secretion is freely promoted from the first—a fact of considerable importance in cases of renal inadequacy, whether this condition be dependent on a temporary cause such as antecedent congestion resulting from pressure, or be due to one or other of the chronic forms of renal disease so frequently to be met with in middle-aged patients. 5. Viewed as a mechanical agent, the enclosed fluid by its mere bulk assists in restoring the balance of intra-peritoneal pressure, disturbed by the removal of a large tumour, and hereby promotes recovery from shock in cases of this nature. 6. As a result of natural gravitation, the water, by displacing the intestinal coils from the pelvic cavity, certainly tends to prevent the formation of adhesions in this situation. 7. Finally, by affording a liquid medium throughout the peritoneal cavity, it diminishes friction and consequent irritation between opposed serous surfaces, intestinal or other, during the first twenty-four hours or so after operation, thereby lessening pain, averting the risk of adhesions, and generally promoting ease and smoothness of recovery.

In conclusion, I may state that my views regarding the value of the treatment in question are founded, not only upon the cases here dealt with, but, further, upon the experience of equally satisfactory results obtained in numerous operations for various abdominal conditions other than those now under consideration. It is hardly necessary to point out that the immediate closure of the abdominal cavity here advocated is, of course, contra-indicated in cases complicated by antecedent intra-peritoneal sepsis at the time of operation.

Manchester-square, W.

[5] The hot water used for this purpose has in every instance been obtained from the usual domestic boiler supply, its temperature being regulated when necessary by the addition of ordinary cold tap water.

ON THE PATHOLOGY OF RECURRENT APPENDICITIS.[1]

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY, AND LECTURER ON OPERATIVE SURGERY, OWENS COLLEGE.

OUR knowledge of the pathology of recurrent appendicitis until quite recently was very imperfect, but it is now much more complete since it has become the custom to employ operative measures for its relief, for opportunities are offered us of studying the changes which take place in the appendix at an early stage in the course of the disease. The following remarks are based on the conditions which were found to be present in twenty cases treated by operation, details of which are given in the accompanying table. Of the 20 cases, 7 occurred in females and 13 in males. The youngest patient was ten and the oldest was forty-four years of age. In 15 of the cases the patients were between fifteen and thirty years of age. In all the specimens examined the appendix showed evidences of chronic inflammatory changes, its coats — mucous, muscular, and peritoneal — being all thickened. In some cases its lumen was uniformly narrowed and almost obliterated; in others it was partially or completely occluded at some point and dilated on the distal side of the obstruction, occasionally forming when the occlusion was complete a cystic cavity of some dimensions. In many instances it was considerably shortened, measuring only from 1 in. to 1½ in. in length, instead of from 3 in. to 4 in., its normal length. It was frequently found to be bent on itself and bound down by adhesions, in one case the tip almost touching the cæcal end of the process. The contents of the appendix consisted either of clear mucus or of a muco-purulent fluid; in two cases a hard fæcal concretion was present in its interior, and in another a concretion, which had ulcerated through its wall, was found in an abscess cavity external to it. In most cases the inflammatory changes were not confined to the appendix itself, for evidences of appendicular peritonitis were generally found to be present, the peritonitis being usually of the adhesive character, the inflammatory exudation which had been poured out round the appendix having undergone organisation and forming adhesions. These were often very firm and extensive, surrounding the appendix and fixing it to the parietal peritoneum, omentum, cæcum, or small intestine. In some instances they were present after a second attack, as in Case 5; in other instances, they were absent after many attacks, as in Cases 8 and 15, where the appendix did not show the slightest trace of an adhesion. When exceptionally dense and extensive complete obstruction of the bowels may be produced from inclusion and compression of a coil of small intestine in the adhesions, and if the condition is incapable of relief by operation the result is necessarily fatal. This happened in Case 18, the attack, which was the third, being accompanied by all the symptoms of acute obstruction, which was the predominant feature in the case. On opening the abdomen the appendix and cæcum were found surrounded by an extensive mass of dense adhesions, included in which were several coils of small intestine, so firmly and so intricately matted together that it was quite impossible to liberate them. In some instances the peritonitis was of the suppurative character, pus having formed in the neighbourhood of the appendix. This complication was met with in

[1] A communication read before the Manchester Pathological Society on April 14th, 1897.

Hosted by Google

eight of the twenty cases. In six of these the suppuration was localised, an encysted intra-peritoneal abscess being present; in two cases the suppuration was general, there being well-marked evidences of diffuse purulent peritonitis. When suppuration takes place it is often secondary to ulceration and perforation of the walls of the appendix, followed by the escape of its contents, for in one case, on evacuating a collection of pus, a large fæcal concretion came away with the discharge (Case 19). In two instances, complicated by the formation of abscess, where the appendix was exposed and removed a ragged perforation was found in its walls (Cases 8 and 11). In another instance (Case 5) the appendix, though not actually perforated, was extremely thinned at one point, which was found to correspond with an ulcer involving its mucous and muscular coats. It has been shown that without any perforation of the appendix suppuration round it may be due to micro-organisms invading its walls and passing through them into the peritoneal cavity. It is a well-known fact that in a state of health bacteria are almost constantly present in the interior of the appendix, as well as in other parts of the intestine, without causing any harm. If, however, the vitality of the walls of the appendix—as of any portion of the intestine—becomes impaired from any cause, as in the case of one which has become the seat of recurring attacks of inflammation, its resisting power is diminished. Under these circumstances the bacteria, becoming virulent, may invade and penetrate its coats, exciting peritonitis, which is often of the suppurative variety.

As regards the course of these cases, if left to themselves the attacks of appendicitis may recur at irregular intervals for years, and ultimately a cure may take place by a gradual process of obliteration of the lumen of the process and its conversion into a fibrous cord. Suppuration may, however, at any time occur; if an encysted abscess forms, after the evacuation of its contents, the appendix usually shrivels up, becoming obliterated and causing no further trouble. On the other hand, if the suppuration is diffuse—i.e., if there is general purulent peritonitis—the result will probably be fatal. Another complication which may occur, as already mentioned, is intestinal obstruction from compression of a coil of bowel by the adhesions so often present. Of the various theories advanced to account for the onset of appendicitis, the most probable is that which regards the appendix as a diverticulum which readily allows of the accumulation and stagnation of fæcal matter. This mingling with the secretion from its mucous lining and undergoing fermentative or putrefactive changes sets up a catarrhal inflammation, which may be followed by ulceration and perforation or by thickening of its walls, the latter condition being the one most commonly met with in the recurrent form of the disease. The fæcal concretions found in its interior are probably the consequence, not the cause, of the inflammation, being due to inspissation of its contents; but once formed there they no doubt tend to excite and keep up the recurrent attacks. Though foreign bodies rarely lodge in the appendix this happened in one instance (Case 1), the patient being a female, aged twenty-seven years, who for about two years had suffered from frequent attacks of appendicitis. At the end of this period an abscess formed in the right iliac fossa, and at the bottom of the cavity a pin was found, the head of which was encrusted with a deposit of calcareous matter. The appendix was surrounded by a mass of old adhesions and its lumen was obliterated almost up to its origin from the cæcum.

Manchester.

TABLE OF TWENTY CASES OF RECURRENT APPENDICITIS.

No.	Date of operation.	Sex.	Age.	Duration of symptoms.	Number of attacks.	Condition of the appendix.
1	June, 1893	F.	27	2 years	About 10	Appendix surrounded by adhesions and almost obliterated; pin found in abscess cavity adjacent to it.
2	June, 1894	M.	10	10 months	2	Small abscess in close proximity to appendix, which was not seen.
3	June, 1895	M.	18	6 months	3	Appendix surrounded by dense adhesions and difficult to recognise; lumen almost obliterated.
4	January, 1896	M.	26	12 months	3	Appendix constricted at its neck; contained a hard, fæcal concretion.
5	January, 1896	F.	29	4 months	2	Appendix occluded at its origin and distended with mucoid fluid; wall much thinned at one spot; numerous adhesions.
6	February, 1896	M.	29	6 months	2	Small abscess in close proximity to appendix, which was not seen.
7	February, 1896	M.	18	10 months	6	Appendix constricted at its origin and sharply bent on itself; distended with muco-purulent fluid.
8	March, 1896	F.	16	Several years	Numerous	Appendix perforated; diffuse purulent peritonitis; no trace of adhesions.
9	March, 1896	M.	26	3 years	Numerous	Large abscess round appendix.
10	March, 1896	F.	25	3 years	5	Appendix occluded at its origin and dilated beyond; contained muco-purulent fluid.
11	April, 1896	M.	20	2 years	Numerous	Appendix perforated; large abscess round it; numerous adhesions.
12	May, 1896	M.	25	2 years	Numerous	Appendix contained a hard concretion; surrounded by dense adhesions.
13	September, 1896	M.	16	9 months	3	Appendix occluded at its middle; dilated beyond and distended with mucoid fluid; numerous adhesions.
14	November, 1896	F.	16	10 months	3	Appendix occluded below its middle; dilated beyond and distended with mucoid fluid; a few adhesions.
15	December, 1896	F.	27	15 months	5	Condition as in No. 14, except that there were no adhesions.
16	January, 1897	M.	44	2 years	3	Small abscess in close proximity to appendix, which was not seen.
17	February, 1897	M.	32	6 years	4	Appendix surrounded by dense adhesions; lumen almost obliterated.
18	February, 1897	M.	28	9 months	3	Appendix lost in mass of dense adhesions, in which coils of small intestine were included and constricted.
19	March, 1897	M.	12	6 months	Numerous	Appendix perforated; diffuse purulent peritonitis; fæcal concretion escaped with the pus on opening abdomen.
20	March, 1897	F.	30	2 years	4	Appendix occluded below middle, bound down by adhesions, and sharply bent upon itself; contained mucoid fluid.

A CASE OF TRAUMATIC TETANUS TREATED SUCCESSFULLY BY ANTITOXIN.

BY ALBERT J. CHALMERS, M.D. VICT., F.R.C.S. ENG.,
ANÆSTHETIST TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

IN view of the recent progress in the antitoxin treatment of disease and the need of recorded cases of tetanus treated thereby, the following account may be of some interest.

A man, aged forty-eight years, while working a crane at the Liverpool Docks in June of last year caught the end of the middle finger of his left hand in the cogs of a wheel, and this destroyed the whole of the terminal and part of the middle phalanx of that digit. He went at once to the Royal Southern Hospital, was treated antiseptically, and this treatment was being repeated every alternate day. On the sixth

Hosted by Google

day after the accident he complained of pain and stiffness in the jaw and throat. This gradually became worse, until he had difficulty in eating, drinking, and in opening his mouth. He then sent for his medical adviser, Mr. Campbell, of High Park-street, and was treated for eight days with chloral hydrate and bromide of potassium, but did not improve. On the contrary, his jaws became more fixed and he became quite unable to swallow solids, though still able with difficulty to manage liquids. He suffered also from spasms, which, at first few in number and slight in effect, gradually increased in frequency and violence, and were readily produced by any slight noise, movement, or excitement. At this time I was requested to see him with Mr. Campbell, and this I did on the fourteenth day of illness. He was suffering from tetanus, having spasms about once in three minutes. The muscles of his jaws, abdomen, and legs were hard and firm, but those of his arms were softer. There was marked opisthotonos. His mouth could only be opened very slightly, and there was much difficulty in deglutition, only a small quantity of fluid being swallowed at a time. The least excitement or noise immediately caused a spasm. His temperature was 98 8° F. and his pulse 120. The bowels were constipated and the urine scanty, highly coloured, and full of urates. The terminal and half the second phalanx of the middle finger of the left hand were missing, while the stump ended in an unhealthy-looking wound, through which the bone protruded for about one-eighth of an inch. There was also a cut upon the first phalanx of the same finger. I suggested that as he was suffering from a chronic form of tetanus he would be a suitable subject for the antitoxin treatment, and, considering the bad condition of the wound on the finger, together with the cut on the first phalanx, that it would not be unreasonable to remove that digit at the metacarpo-phalangeal articulation. Mr. Campbell kindly consented to this line of treatment and requested me to get some antitoxin. After some difficulty I was able to get some of Roux's antitoxin for tetanus, which was kindly given to me by Dr. Carter, of Rodney-street. I then removed the stump of the finger at the metacarpo-phalangeal articulation and then injected fifteen grains of Roux's antitoxin (which was all I possessed) into the gluteal region. Though placed fully under the influence of chloroform the stiffness did not depart from the patient's limbs or jaws. For some time after the narcosis he was free from spasms, but gradually they returned to their former frequency and strength On the next morning (Sunday) there were no marked rise in temperature and no increase in the quantity of urine, which remained as before. The slightest touch gave rise to spasm, with marked opisthotonos. The risus sardonicus was marked, while the jaws could be opened about a quarter of an inch or less, and there were sordes on the lips. On the evening of this day the patient was evidently worse, swallowing being more difficult. During the course of the next day (Monday) I was able to obtain some of Tizzoni's antitoxin from Messrs. Allen and Hanburys, Tizzoni's preparation being the one I particularly desired to use. During Sunday night and Monday the patient became rapidly worse, swallowing being almost impossible, and the spasms being even more frequent and stronger. At 6 P.M. on Monday the antitoxin arrived, and I injected at once thirty grains of the sixty grains which I had obtained into the loose subcutaneous tissue of the abdominal wall. The patient's temperature was 100·2°, and his pulse 120. On Tuesday morning the spasms were a little less frequent and not quite so violent, and the patient was able to swallow somewhat better. In the evening the spasms were only once in ten minutes on the average, and not nearly so strong; swallowing was the same as in the morning. The temperature was 99°, and the pulse 100. I then injected fifteen grains more of Tizzoni's antitoxin. On Wednesday night the patient was decidedly improving, and had had only about forty spasms in the twenty-four hours. The pulse was 96, and the temperature 98·4°. He could swallow much better, and could open his jaws wider than before. I injected about eight grains of Tizzoni's antitoxin. On Thursday night the patient was much improved, swallowing fluids without much difficulty. There had been only four attacks of spasms during the previous twenty-four hours. The pulse and temperature were normal. On Friday night his condition was very satisfactory; there had been no spasm during the previous twenty-four hours and swallowing was again better, though no solids had been given him. The muscles of the limbs and jaws were very stiff. The jaws could be opened rather better. From this time the patient gradually improved, and by means of massage the stiffness passed off from the legs, though he had difficulty in walking for quite six weeks. The stiffness in the jaws lasted much longer, being complained of two months later. In about a week he was able to swallow solids, but it was long before any strength came back to him, the wasting being marked. In fact so run down was he that the wound caused by the removal of the finger remained quite passive for over a fortnight, with no attempt at healing and no discharge. The stitches were removed and the wound rubbed with pure carbolic acid, and as the patient gradually improved in strength so the wound gradually healed in another three weeks without any further trouble except the application of pure carbolic acid at intervals.

Remarks.—The incubation in the above case appears to be very definite—viz., six days—and the antitoxin treatment was commenced upon the fourteenth day after the accident and the eighth after the first symptoms by a small injection of Roux's antitoxin. But it was not till the sixteenth day after the accident and the tenth day after the first symptoms that treatment by means of Tizzoni's antitoxin was begun. In all the patient received fifteen grains of Roux's and fifty-three grains of Tizzoni's antitoxin. No apparent effect was caused by the Roux antitoxin, as the transient improvement might be justly assigned to the chloroform. The effect of Tizzoni's antitoxin was astonishing, for the patient appeared to be rapidly sinking and all hope of curing him had been abandoned. It would be unfair to draw any inferences concerning the relative merits of the two antitoxins from the above case; but it is interesting to note that Kanthack, in a paper on the Value of Serum Treatment in Tetanus in the *Medical Chronicle*, April–September, 1895, p. 92, gives a list of 54 cases of tetanus treated by various antitoxins, and among these he finds that 31 cases were treated with Tizzoni's with a result of 23 cures and 8 deaths, or a mortality of 25·8 per cent., while with Roux's 13 cases were treated, 4 being cures and 9 deaths, or a mortality of 69 23 per cent. Further on (page 101) he says: "Of the 31 cases treated with Tizzoni's antitoxin 3 only can be considered test cases, and of these only one survived, while all of the Roux's acute cases died." I found no untoward symptom arise from the use of either antitoxin. The only drawback in the use of the antitoxins was that they were only soluble with difficulty in the sterilised water, particularly the Tizzoni. I may mention that I last saw the patient about a month ago, and he was then in good health. In conclusion, I wish to draw attention to the trouble I had in obtaining any tetanus antitoxin. During the Saturday and the Monday morning I attempted in many ways to get some, and signally failed, till some unknown person, to whom I am most grateful, wired to me to try Messrs. Allen and Hanburys', which I did with success. I think that it is a great mistake that a supply of this antitoxin is not kept in England in some way that it can readily be obtained by any medical man.

Liverpool.

A NOTE ON THE PHENOMENA OF MESCAL INTOXICATION.

BY HAVELOCK ELLIS,

EDITOR OF THE "CONTEMPORARY SCIENCE SERIES."

MESCAL buttons (the fruit of Anhalonium Lewinii) are eaten by the Kiowa and other Indians of New Mexico, and their use is connected with religious ceremonial. Recently the extraordinary vision-producing properties of this substance have been investigated in America by Prentiss and Morgan,[1] and more especially by Weir Mitchell, who has published a very interesting record of the marvellous colour visions by which he was visited when under the influence of mescal.[2] There seems, however, to be at present no record of any experiment in the use of mescal in the production of visual phenomena carried out on this side of the Atlantic. The phenomena are certainly of much interest—perhaps even more so to the psychologist than to the physician, notwithstanding remarkable results recorded in the treatment of neurasthenia, &c.—and it may therefore be worth while to record briefly my personal experience with mescal. I will refrain here from describing the visions themselves, which were, perhaps, less wonderful in my case than in that of Dr. Weir Mitchell (who, as he admits, is a

[1] Therapeutic Gazette, Sept. 16th, 1895.

Hosted by Google

favourable subject for visions, while I am not), and speak chiefly of other phenomena which were either unnoticed or unexperienced by the American observers.

On Good Friday, being entirely alone in quiet London rooms, I made an infusion of three buttons (a full dose) and took it in three portions at intervals of an hour between 2 30 and 4.30 P.M.[3] The first noteworthy result (and the only one of therapeutic interest which I have to record) was that a headache which had been present for some hours and showed a tendency to aggravation was immediately relieved and speedily dissipated. There was slight drowsiness before the third dose was taken, but this speedily passed off and gave place to a certain consciousness of unusual energy and intellectual power, which also quickly passed off, and was not marked and prolonged, as with Dr. Weir Mitchell. So far no visual phenomena had appeared, even when the eyes were closed for several minutes, and there was yet no marked increase of knee-jerk; there was, however, a certain heightening of muscular irritability, such as may be noted when one has been without sleep for an unusual period. The pulse also began to fall. After the third dose I was still feeling on the whole better than before I began the experiment. But at 5 P.M. I felt slightly faint, and it became difficult to concentrate my attention in reading; I lay down and found that the pulse had now fallen to 48, but no visual phenomena had yet appeared. At 6 P.M. I noticed while lying down (in which position I was able to read) that a pale violet shadow floated over the page. I had already noted that objects which were not in the direct line of vision showed a tendency to be heightened in colour and to appear enlarged and obtrusive, while after-images began to be marked and persistent. At 6 P.M. there was a slight feeling of faintness as well as of nausea, and the first symptoms of muscular incoördination began to appear, but there was no marked discomfort. By 7 P.M. visions had begun to appear with closed eyelids, a vague confused mass of kaleidoscopic character. The visual phenomena seen with open eyes now also became more marked, and in addition to the very distinct violet shadows there were faint green shadows. Perhaps the most pleasant moment in the experience occurred at 7.30 P.M., when for the first time the colour visions with closed eyes became vivid and distinct, while at the same time I had an olfactory hallucination, the air seeming filled with vague perfume. Meanwhile the pulse had been rising, and by 8 30 P.M. had reached its normal level (72 in the sitting posture). At the same time muscular incoördination had so far advanced that it was almost impossible to manipulate a pen, and I had to write with a pencil; this also I could soon only use for a few minutes at a time, and as I wrote a golden tone now lay over the paper, and the pencil seemed to write in gold, while my hand, seen in indirect vision as I wrote, looked bronzed, scaled, and flushed with red. Except for slight nausea I continued to feel well, and there was no loss of mental coolness or alertness. When gazing at the visions with closed eyes I occasionally experienced slight right frontal headache, but as I only noticed it at these times I attribute this mainly to the concentration of visual attention. In one very important particular my experience differs from Dr. Weir Mitchell's. He was unable to see the visions with open eyes even in the darkest room. I found it perfectly easy to see them with open eyes in a dark room, though they were less brilliant than when the eyes were closed. At 10 P.M., finding that movement distinctly aggravated the nausea and faintness, I went to bed, and as I undressed was impressed by the bronzed and pigmented appearance of my limbs. In bed the nausea entirely disappeared, not to reappear, the only discomfort that remained being the sensation of thoracic oppression, and the occasional involuntary sighing, evidently due to shallow respiration, which had appeared about the same time as the vision began. But there was not the slightest drowsiness. This insomnia seemed to be connected less with the constantly shifting visions, which were always beautiful and agreeable, than with the vague alarm caused by thoracic oppression, and more especially with the auditory hyperæsthesia. I was uncomfortably receptive to sounds of every kind, and whenever I seemed to be nearly falling asleep I was invariably startled either by the exaggerated reverberation of some distant street noise (though the neighbourhood was even quieter than usual), or, again, by the mental image (not hallucination) of a loud sound, or, again, as I was sometimes inclined to think, by actual faint hallucinatory sounds; this, however, was difficult to verify. At a later stage there was some ringing in the ear. There was slight twitching of the larger muscles of the legs, &c., and before going to bed I had ascertained that the knee-jerk was much exaggerated. The skin was hot and dry. The visions continued. After some hours, tired of watching them, I lighted the gas. Then I found myself in a position to watch a new series of vivid phenomena to which the previous investigators had not alluded. The gas—i.e., an ordinary flickering burner—seemed to burn with great brilliance, sending out waves of light which extended and contracted rhythmically in an enormously exaggerated manner. What chiefly impressed me, however, were the shadows which came in all directions, heightened by flushes of red, green, and especially violet. The whole room then became vivid and beautiful, and the tone and texture of the whitewashed but not remarkably white ceiling was immensely improved. The difference between the room as I then saw it and its usual appearance was precisely the difference one may often observe between the picture of a room and the actual room. The shadows I saw were the shadows which the artist puts in, but which are not visible under normal conditions of casual inspection. The violet shadows especially reminded me of Monet's paintings, and as I gazed at them it occurred to me that mescal doubtless reproduces the same conditions of visual hyperæsthesia, or rather exhaustion, which is certainly produced in the artist by prolonged visual attention (although this point has yet received no attention from psychologists). It seems probable that these predominantly violet shadows are to some extent conditioned by the dilatation of the pupils, which, as the American observers had already noted, always occurs in mescal intoxication. I may remark in this connexion that violet vision has been noted after eye-operations; and Dobrowolsky[4] has argued that a necessary condition for such vision is the dilatation of the pupils produced by atropine, so that the colour vision (chiefly violet, though to some extent of other colours) is really of the nature of an after-image due to bright light. Dobrowolsky's explanation seems to fit in accurately with my experiences under mescal.

I wished to ascertain how the subdued and steady electric light would influence vision and passed into the next room. Here the richly coloured shadows, evidently due to the stimulus of the flickering light, were not obtrusive; but I was able to observe that whatever I gazed at showed a tendency to wave or pulsate. The curtains waved to a marked extent. On close inspection I detected a slight amount of real movement, which doubtless increased the coarser imaginary movement; this latter showed a tendency to spread to the walls. At the same time the matting on the floor showed a very rich texture, thick and felted, and seemed to rise in little waves. These effects were clearly produced by the play of heightened shadows on the outskirts of the visual field. At 3.30 A.M I found that the phenomena were distinctly decreasing, and soon fell asleep. Sleep was apparently peaceful and dreamless, and I rose at the usual hour without any sense of fatigue, although there was a slight headache. A few of the faint visual phenomena with which the experience had commenced still persisted for a few hours.

Motor incoördination and the thoracic symptoms of cardiac and respiratory depression were in my case the only really unpleasant symptoms of the experiment. They are barely noticed by the American observers, who emphasise the gastric symptoms and headache, in Dr. Weir Mitchell's case persisting for several days. In my case there were practically no unpleasant after results. I cannot say how far the method of administration affected this result. I took the drug in infusion; previous experimenters used an extract or a tincture, or else ate the buttons.

It cannot be said (from my experience) that the pleasure of mescal intoxication lies in any resultant passive emotional state such as is produced by tea or alcohol, but strictly in the enjoyment of the colour visions produced. Attention is impaired (and one realises under the influence of mescal how largely attention is a matter of coördination), but intellectual judgment remains unimpaired. The visions, as I recall them, seem to me (unlike most dream visions) as beautiful in memory as when I experienced them. The sensory phenomena seem to be due to great and general disintegration and exhaustion of the sensory apparatus; in

[3] I first cut up the buttons into small fragments and I poured on boiling water twice; a single infusion, as I have since found in the case of other persons, is inactive.

[4] Ueber die Ursache der Erythropsie, Archiv für Ophthalmologie, vol. xxiii., p. 213.

Hosted by Google

a slighter degree the same phenomena are found in neurasthenia, even the colour vision. I am convinced that all the senses were more or less affected. There were vague dermal sensations, and the body felt unfamiliar to touch, just as everything seemed delightfully unfamiliar to the sense of vision. I noticed, also, that any marked casual stimulation of the skin produced other sensory phenomena—a heightening of the visions or an impression of sound. This is a phenomenon which may throw an interesting light on the synæsthesiæ or "secondary sensations."

The phenomena of mescal intoxication are thus mainly a saturnalia of the specific senses, and chiefly an orgy of vision. Personally, I have found the penalty of a single dose surprisingly light, though, having learned what the experience has to teach, I have no special inclination to renew it. But I fully agree with Dr. Weir Mitchell, that there is every likelihood that mescal will become popular. It certainly has a great future before it with those who cultivate the vision-breeding drugs. At the same time it is of no little interest to the physiologist and psychologist.

Lelant, Cornwall.

IMPLICATION OF THE STERNO-CLAVICULAR JOINT OCCURRING DURING THE COURSE OF GONORRHŒA.

BY GEO. HENRY EDINGTON, M.D. GLASG., M.R.C.S. ENG.,
SURGEON TO GLASGOW CENTRAL DISPENSARY.

A MAN, aged twenty-seven years, was seen by me at the Glasgow Central Dispensary on Dec. 16th, 1896, through the kindness of my colleague, Mr. Dryden Moffat. Three weeks previously he had contracted gonorrhœa, but the discharge had ceased at the end of a week and there was none at the time he came to the dispensary. When the gonorrhœa had lasted for one week he began to complain of pain in the neighbourhood of the left shoulder. The pain shifted along the clavicle, and finally he observed a painful swelling over the left sterno-clavicular articulation. At the same time the left testicle became swollen. No other joints were affected; he thought himself to be suffering from rheumatism, but medicines which he took were without effect. He had had gonorrhœa four years previously, but it did not cause him much inconvenience. He had never had any sore on the penis nor had he ever observed any syphilitic manifestations. His condition on Dec. 16th was as follows. He was very pale and thin and looked ill. He felt weak and had no appetite. There was swelling over the left sterno-clavicular articulation, entirely obscuring the surface anatomy of the part. The swelling extended on to the sternum towards the middle line and seemed probably sub-periosteal at this part. The skin was dusky-red and great pain and tenderness were complained of in the part. Any movements of the left upper extremity were accompanied by great pain and were on that account of a limited nature. The diagnosis lay between sub-periosteal suppurating gumma over the manubrium and pyæmic affection of the articulation. Against the former was the absence of history or signs of syphilis, while in favour of the latter was the fact of the patient having contracted a gonorrhœa a week before the commencement of the joint affection. It was decided to put him on iodide of potassium on the chance of it doing good in either affection, and he accordingly received ten grains thrice daily with fifteen grains of bicarbonate of potash. The arm was supported in a sling. In three days after this (Dec. 19th) the dusky-red swollen area was white, the swelling was very much down, the pain was gone, and the patient was feeling much better generally. He was still unable to put on his coat on account of stiffness with pain on exertion. On Dec. 23rd the swelling was again present, and hot fomentations were ordered, while he was directed to continue the iodide mixture. The swelling at this date was situated definitely over the joint. On Jan. 6th, 1897, the swelling was more prominent and fluctuant. A small incision let out a few drops of reddish-yellow turbid serum, and through the wound greyish granulations prolapsed. A probe passed both outwards and inwards, along underneath the skin for an inch or so, but not into the joint. By another week the patient could move his arm freely, the swelling was very much lessened, and at the seat of incision was a small bud of granulations. At the end of January there was still a sinus leading backwards to the joint. Below the articulation there was some thickening of the sternum, while the end of the clavicle was pulled upwards, apparently from softening of the ligaments. The joint was well defined in its surface anatomy. On account of the sinus persisting he was sent into the Western Infirmary, where the granulations were scraped out under chloroform by Dr. Hector Cameron. In March of the present year (1897), when I last saw the patient, the following note was made:—The sinus had healed; there was some projection upwards of the sternal end of the clavicle, with some fixation of the joint and soft grating on movement (extra articular?). The patient was feeling quite well again.

Remarks.—The case seems to me to be of sufficient interest to warrant my publishing it, my object in so doing being to suggest the connexion between the joint affections in gonorrhœa and pyæmia. Unfortunately, the surroundings of the case prevented my investigating it bacteriologically, and thus I am unable to say what micro-organisms, if any, were present in the joint effusion. The characters of the affected part both before and at the operation resembled those seen in pyæmia, added to which is the fact of the common selection of the sterno-clavicular articulation in that constitutional condition. The effect of medicinal treatment is interesting, the exhibition of iodide being followed by very sudden improvement, and this again by gradual progression towards suppuration. The behaviour of the part after operation was very satisfactory, and the patient was left very little the worse for his illness. Without drawing conclusions from a single case I have noted the following points as being of interest:—(1) Early appearance of joint complication in the course of the disease (seventh day), associated with orchitis; (2) acute process, affecting periarticular tissues subsequently; resulting deformity of joint; (3) response to medicinal treatment and relapse; and (4) subsequent favourable termination of the case after operation.

Glasgow.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF GUNSHOT WOUND PENETRATING THE CHEST: A PATHOGNOMONIC SIGN OF HÆMOTHORAX.

BY W. J. ERNELY SUMPTER, L.R.C.P. LOND., M.R.C.S. ENG.

PENETRATING gunshot wounds of the chest are perhaps sufficiently rare in civil practice to justify a short record of the following case in the columns of THE LANCET.

On April 7th, 1897, I was called to see a man who, it was stated, had just shot himself. I found him lying on his back and evidently much collapsed. On examination a wound was found penetrating the chest wall just two inches above the left nipple in the third intercostal space. The bullet had passed out at the back in a slightly higher position, the wound being just four inches from the spine and five inches from the top of the scapula. The scapula was apparently not damaged, neither were any of the ribs. The former escaped owing to the position of the arm at the time of the injury, as was ascertained later, the left arm having then been raised to a right angle with the trunk and the forearm drawn forward slightly across the chest, to give a support to the pistol which was held in the right hand, and the trigger pulled with the thumb. The weapon was an old Enfield revolver, and the bullet, after penetrating the chest, passed through a notice-board and a wooden partition into an adjoining room, where it was found very much flattened on the floor. The shock was very pronounced, the pulse being very weak and rapid, and at times almost imperceptible. There was very little bleeding externally. On applying a stethoscope to the chest coarse râles were heard all over the left lung below and about the wound, and the breath sounds were markedly deficient. Both wounds were gently examined with the finger, and no extraneous matter being found they were carefully

Hosted by Google

cleansed with a corrosive sublimate lotion and an antiseptic dressing applied, which was retained in position by a broad bandage placed round the chest. After a few days the left chest was strapped in place of the bandage. The progress of the case towards recovery was practically uneventful. More or less pain was felt in the neighbourhood of the wound for several weeks. There was very little cough and scarcely any expectoration. The temperature remained above the normal for nearly a month, and reached 103·6° F. The breath sounds showed a marked improvement during the first week, but after that time progress was not so rapid. The râles gradually disappeared as the effused blood was absorbed. The patient was at first allowed cool drinks freely, and ice to suck. A quarter of a grain of morphia was given hypodermically twice daily for a fortnight, and then every night for ten days longer. When the temperature rose above 101° he was given three grains of quinine in powder twice daily, and later, owing to a marked specific history, he was ordered a mixture of bark, with perchloride of mercury and iodide of potassium. About a fortnight after the accident I was interested to find a marked ecchymosis about the angles of the lower ribs, which extended down towards the loins. This sign was regarded by Valentine as pathognomonic of blood effused within the chest, and is mentioned in Guthrie's Commentaries. It was, as he says, "very dissimilar to that which occurs after a blow or wound, and which takes place shortly after an accident, being around the wound if there be one, and extending from it. The patient also complains of pain when the bruised part is pressed by the fingers, and these characters are not observed in the ecchymosis, the sign of effusion. Its colour is identical with that which appears on the abdomen of persons some time after death, a bright violet (*violet très-éclairci*) appears about ten days after the receipt of the injury, sometimes later." I last saw the patient on May 18th. Both wounds were then soundly healed, the breath sounds were scarcely as free over the base of the left lung, as over the right. No râles could be heard, but there was some increased resistance on percussion. He was able to get about well.

Sherringham, Norfolk.

A CASE FOR DIAGNOSIS.

By RAYMUND H. PHILLIMORE, M.D.

I ATTENDED a case last year which presented so many curious features that I think it may be of sufficient interest to lay before the readers of THE LANCET. Briefly, the history of the case was as follows.

On Feb. 29th, 1896, I was summoned to attend a man, aged nineteen years. He was a total abstainer, with a family history of phthisis. He complained of pain in the right side, vomiting, rigors, and constipation. He suffered from a most intense and persistent frontal headache. He said that he had not been feeling well for ten days or a fortnight. Physical examination disclosed a liver greatly enlarged. It extended from the lower border of the fifth rib to nearly the level of the umbilicus in the middle line and below that level in the right flank. It also extended three or four inches to the left of the middle line. The organ was very sensitive on palpation. The spleen was also enlarged. A herpetic eruption was present round the lips. The heart and lungs were normal. The temperature was 101·4° F., the pulse was 94, and the respiration was 20 per minute. On March 1st there occurred violent epistaxis with severe headache. On the 2nd the patient had two chills; the headache was unrelieved by ordinary treatment. The temperature was 101·5° in the morning, but it became normal in the evening. On the 3rd a few suspicious spots were observed on the abdomen. The temperature in the morning was 99° and in the evening 100·8°. On the 4th four rigors occurred. The tongue was dry, brown, and fissured. The temperature in the morning and evening was normal. On the 5th there was epistaxis. On the 6th pronounced jaundice was present. Two stools were passed. The temperature in the morning was 103·6°, but in the evening it was normal. On the 7th epistaxis occurred. On the 8th the patient suffered from distressing rigors with a flushed face, followed by profuse perspiration simulating a malarial attack. In the morning the temperature were 100° and in the evening it was 99·8°. On the 9th and 10th there were rigors. On the 11th the patient again suffered from rigors. He passed three stools on this date. On the 12th and 13th rigors again occurred. The abdomen was tympanitic. On the 14th there were hiccough, vomiting of bile, and enlargement of the superficial thoracic veins on the right side. The rigors were followed, as before, by profuse perspiration. The patient was continually drowsy. The conjunctivæ were greenish-yellow in colour. He complained of severe pain in the right side. Albumin was present in the urine, but not in excessive quantity. Delirium supervened. The morning and evening temperatures were 100° and 100·4° respectively. On the 15th at 9 A.M. the temperature was 107°, the respiration was 28 per minute, and the pulse was 116. The patient was delirious. The heart's action was feeble and intermittent. Hiccough was present. At 3 P.M. the temperature was normal; there was vomiting. At 7 P.M. the temperature was 102 and the respiration was 5 per minute. On the 16th, 17th, and 18th persistent chills occurred and there was rapid emaciation. On the 19th an attack of epistaxis occurred, with stertorous breathing (18 per minute); he was very restless and vomited. The morning and evening temperatures were 104° and 102° respectively. On the 20th at 9 A.M. the temperature was 99·5°, the pulse was 110, and the respiration was 18, and at 5 P.M. they were 101°, 132, and 28 respectively. At 7 P.M. sudden collapse and death occurred.

Was this a case of hypertrophic cirrhosis of the liver complicated with typhoid fever of an atypical form? The sudden collapse might then be attributed to perforation of the bowel with emptying of contents into the peritoneal cavity. Unfortunately no post-mortem examination was allowed. I may add that the patient received the attention of a regular hospital nurse.

Cookshire, Quebec, Canada.

AVULSION OF THE UTERUS.

By E. HICKSON SMITH, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT SURGEON TO THE LONGTON HOSPITAL.

ON the morning of Dec. 29th, 1896, I was sent for in haste to go five miles into the country to see a patient who had just been confined. On my arrival at the house the midwife informed me that the child had been born two hours previously on the floor while the mother was on her hands and knees. After separating the child and getting the patient into bed she found a large lump protruding from the vagina, which she thought was the head of another child, and consequently pulled on it for three-quarters of an hour until she had dragged it away. I immediately examined this, and found it to be the inverted uterus. This I turned back again, and found it was the whole of the uterus and cervix, with its peritoneal covering, and one broad ligament and Fallopian tube, without the ovary. The broad ligament of the other side was congenitally absent. On examining the patient I perceived her to be suffering from shock. On inserting my finger into the vagina, it moved freely about among the intestines, and the absence of the uterus and cervix was distinctly apparent. The hæmorrhage was but slight, and gave no trouble. I feared that the natural result of such a catastrophe would be prolapse of the bowels and general peritonitis. I therefore kept the patient on her back, put in an antiseptic plug, and in order to quiet the peritoneum administered morphia, and ordered a strictly milk diet. Contrary to what might have been expected no serious symptoms occurred. The peritoneum closed up and the top of the vagina cicatrised over. In about three weeks the patient was able to get up and go about. On visiting her three months later she was in her usual health and the vagina was then a *cul-de-sac*. I am sure that many members of the medical profession will be interested to hear of this remarkable case and recovery.

Longton, Staffordshire.

PRESENTATIONS TO MEDICAL MEN.—Dr. Robert Fullerton, surgeon to the Throat Department of the Greenock Infirmary, has been presented with a solid silver tray by the staff of the hospital as a token of esteem.—Surgeon-Captain Forrest, of the 3rd Lanark Rifle Volunteers, has been presented with a handsome surgical case by the members of his ambulance class.

ROYAL FREE HOSPITAL.

LARGE FIBRO-SARCOMA OF THE SCIATIC NERVE; REMOVAL; RECOVERY.

(Under the care of Mr. JAMES BERRY.)

PRIMARY sarcoma of the peripheral nerves is rare, and comparatively few examples of it have been recorded. G. H. Hume[1] described three cases, in two of which the great sciatic was affected, and in one the internal popliteal; the first case resembled the one recorded below in many respects; the patient was a man, aged twenty-four years, and a large portion of the sciatic nerve had to be removed, yet walking was possible, but sensation of the outer side of the leg did not return. A. G. Gerster[2] after removing a sarcoma with a portion of the peritoneal nerve, sutured the free ends of the nerve, but without return of function. G. Lawson[3] removed a sarcoma growing in the optic nerve, but recurrence rapidly took place. D. Bolding[4] removed a tumour of the great sciatic with five inches of the nerve, but recurrence rapidly took place.

A married woman, aged nineteen years, was admitted into the Royal Free Hospital on May 26th, 1896, complaining of a swelling of the left thigh. About eighteen months previously the patient noticed a swelling about as large as an egg situated on the hinder aspect of the left thigh, just above the level of the knee. It was then hard and could not be moved at all. She could assign no cause for its appearance. Ten months before admission, just after the birth of her first child, she had noticed that the swelling was distinctly larger, having extended upwards. It was not until seven months ago that she experienced any pain or inconvenience from the swelling, and even then there was only slight pain and numbness on sitting, but she could lie on that side in bed without any discomfort. A fortnight before coming to the hospital she had felt a rather sharp pain in the back of the thigh on walking. She was sure that she had lost flesh recently. Except for occasional pains and an attack of tonsillitis two years before, which resulted in some deafness, she had always been in very good health. No history indicative of syphilis could be obtained, and her child was strong and well. In the patient's family history there was nothing of importance. On admission the patient was found to be thin. The heart and lungs were normal, and no visceral disease could be detected. There was swelling of nearly the whole of the back of the left thigh, extending from one and a half inches above the knee-joint to the level of the great trochanter. It was most marked internally, especially below, and seemed to be in, or at least attached to, the hamstring muscles, but it was not adherent to the femur or to the skin. It measured twelve inches vertically and six inches from side to side; it was firm on pressure and exhibited coarse lobulation, especially at the lower part. The lower end was hemispherical, with a well-defined edge, and this part was the most movable of the whole tumour. The uppermost portion was in great part covered by the hamstring muscles, so that its outline was not so well defined. The skin over the whole swelling was normal in appearance. Over the greater part of the tumour there was tenderness on pressure. The movements of the hip and knee-joints were perfectly free. There was no wasting below the knee. No enlarged glands could be felt either above or below Poupart's ligament and no tumours were discoverable elsewhere. On measurement the increase in size of the left limb as compared with the right was five and a half inches at the gluteal fold, six inches at the middle of the thigh, and two and a half inches at the junction of the middle and lower thirds of the femur. The patient had no limp in walking and was able to get up every day. On June 8th examination was made by means of the Roentgen rays and a fluorescent screen, and it was found that the tumour was quite transparent to the rays. On the 11th, the patient being under the influence of ether, Mr. Berry made a vertical incision about nine inches in length over the tumour in the line of the great sciatic nerve, commencing over the gluteus maximus. The structures superficial to the growth were cut through, the hamstring muscles being divided, and the tumour on exposure was seen to be encapsuled. On searching for the great sciatic nerve it was found to be completely surrounded by the growth. None of the muscles seemed to be actually infiltrated by the growth, though adherent to it. The tumour was cut into in several places, and as it looked in many parts as if it might possibly be a pure fibroma it was decided to remove the growth in the hope of saving the limb. The incision was lengthened by about seven inches, and then it was possible to see that the tumour had infiltrated the hamstrings at the upper part, so they were cut through close to the tuber ischii and also in the popliteal space. The dissection was carried on well beyond the growth, apparently healthy structures being everywhere cut through. Nearly opposite the middle of the femur the tumour was found to be rather firmly attached to the periosteum by fibrous bands. The growth was separated with great difficulty above, as it had to be dug out from underneath the gluteus maximus, nearly as high as the iliac crest. On cutting into the tumour to release the great sciatic nerve, which traversed it, it was seen that nearly four inches of the middle of the nerve were much infiltrated by the growth. The advisability of amputating was considered, but it was decided to leave the limb, at all events for the time. The affected portion of the nerve was excised with the tumour, and as it was quite impossible to unite the ends of the nerve they were cut quite short above and below. The hæmorrhage was controlled without difficulty, and all the bleeding vessels having been tied the wound was closed by silk sutures, a drainage-tube being inserted. A cyanide gauze dressing was applied and the thigh bandaged so as to approximate the sides of the large cavity which had been left. The leg was wrapped in cotton wool and the opposite limb was bandaged with a flannel roller. The operation was well borne considering its magnitude and lasted ninety minutes. The growth with the muscles attached weighed six and a half pounds and measured thirteen inches in length and five inches in width at the largest part. On microscopic examination the growth was found to consist to a very great extent of firm fibrous tissue, but sarcomatous tissue was present, especially at the upper part where the tumour was softer. After the operation there was some collapse, but it did not last long. Some oozing of blood-stained serum required the application of additional dressing. Nutrient enemata were ordered. On June 12th the patient slept with the help of a hypodermic injection of morphia. She complained of some pain, but was able to take food. In the early morning the temperature rose to a little over 100° F., but fell to normal during the day. On the 13th the wound was dressed and looked well, though there was a good deal of discharge. The foot was quite insensitive to touch. On the 15th the temperature rose a little at night; the previous night it reached 101·5°. She complained of no pain, but said that the left leg felt heavy. On the 17th all the stitches were removed, as the wound had healed by first intention except for a small portion at each end. On the 18th the patient felt very well. On examination for power of movement it was found that, except for mobility at the hip-joint, the limb had no power of motion. As to sensation, it was normal internal to the crest of the tibia from the knee down to the heel. The rest of the foot and the outer part of the leg were quite insensitive. On the 19th the patient was certain that she could feel the warmth of the hand on the outer side of the leg. The temperature was never above 100° at this time. On the 22nd a small patch of skin on the left buttock had sloughed. There was then only a narrow strip on the outer side of the front of the leg where there was no sensation. On the 26th the left leg was massaged; it measured a quarter of an inch less than the right leg round the calf. The left foot was warmer than the right, but had no sensation, which was also absent from the left external malleolus. The whole of the leg possessed sensation, though it was a little imperfect on the outer side.

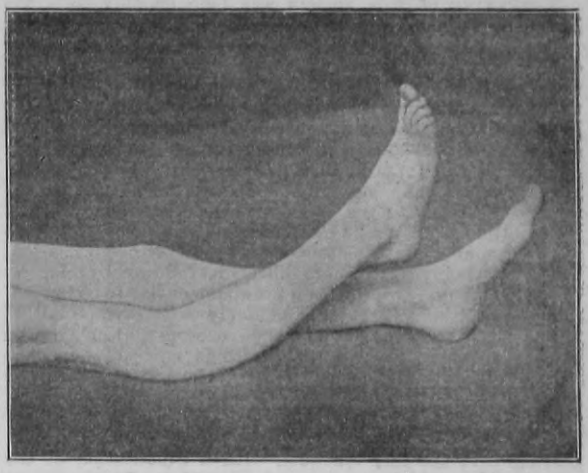
She got up every day. On the 30th the wound had almost healed, and the surface from which the slough came was granulating well. A gutta-percha splint had been applied to prevent foot-drop. On July 6th she was doing well and was able to flex the knee. Sensation was perfect on both sides of the left leg, but was still deficient over the foot. She was able to walk with the help of crutches. On July 31st sensation over the foot had improved, but it was still not perfect. She was able to walk with a stick. On August 24th she seemed quite well and was able to get about without any crutch or stick, the sensation on the foot was practically perfect, and the wound was completely healed. She still wore the gutta-percha splint, and on Aug. 25th went to a convalescent home. The patient has been seen several times since returning from the convalescent home, and she has continued well. Recent inquiries at the address she gave have failed to find her.

Remarks by Mr. BERRY.—The chief points of interest about this case are the unusually large size of the tumour, the slight amount of pain that it had caused notwithstanding the extensive infiltration of the sciatic nerve, and, lastly, the ability of the patient to walk without artificial support after complete removal of the three posterior hamstrings as well as practically the whole sciatic nerve. The diagnosis of the sarcomatous nature of the tumour presented no difficulty, although the exact origin of it was not definitely diagnosed. It was thought before operation that the tumour probably sprang from the inter-muscular fascia of the thigh or from the muscles themselves. Its hardness and its comparatively slow growth led to the belief that it was not of a high degree of malignancy, and that consequently there was a fair prospect that it had not caused secondary deposits. The operation was begun with the expectation that amputation would be necessary on account of the probable involvement of the femoral vessels. It was the freedom of these that determined me to make the attempt to save the limb in spite of the necessary sacrifice of the sciatic nerve and hamstring muscles, and in spite of the enormous size of the wound caused by the removal of the tumour. I hardly expected that the patient would retain, as she has, the power of flexing the knee. This movement she performs solely with the sartorius, which is the only flexor of the knee over which she has any power. Even should an amputation eventually become necessary, on account of the paralysis below the knee, it could be done at a level much below that at which it would have been done if performed for the removal of the tumour. Lastly, the case is an illustration of the fact that many of the sarcomata springing from nerve trunks do not possess a very high degree of malignancy.

GENERAL INFIRMARY, LEEDS.



A CASE OF UNUSUAL DEFORMITY OF THE TIBIA TREATED BY OPERATION.

(Under the care of Mr. W. H. BROWN.)

As the patient in the following case was only sixteen years of age when the accident occurred, the upper epiphysis of the tibia had not joined; it is therefore not improbable that the cause of this interesting deformity was the partial premature union of this epiphysis with the diaphysis—that is to say, that the epiphysis had become united with the shaft anteriorly, so that there the growth of the bone ceased, but that posteriorly the tibia continued to grow. That the knee-joint had been greatly inflamed is shown by the ankylosis which occurred, and it is a fairly common result of inflammation in a joint that an adjoining epiphysis should unite prematurely with its diaphysis. The peculiarity in this case seems to be (if the above explanation is correct) that the union was not equally complete everywhere.

A pit-boy, aged twenty-one years, was admitted to hospital for a tuberculous abscess near the crest of the right ilium. The deformity of the tibia shown in Fig. 1 was said to be the result of a crush between two slack waggons five years previously. The effect of this accident was to confine him to bed for six months, during which time several abscesses formed and burst round the knee-joint. After this he commenced his work, and two years later—that is, three years prior to his admission—his leg commenced to bend forward and had since got gradually worse, although it caused him no pain, and he was able to walk fairly well. The right knee was firmly ankylosed, and there were several scars round about the knee-joint. The leg was muscular, and the length of the tibia and fibula corresponded with those of the sound side. So soon as the abscess near the ilium had healed it was suggested to the patient that the attempt should be made to rectify the deformity of his limb. He readily consented, and accordingly, under an anæsthetic, an osteotomy was under-

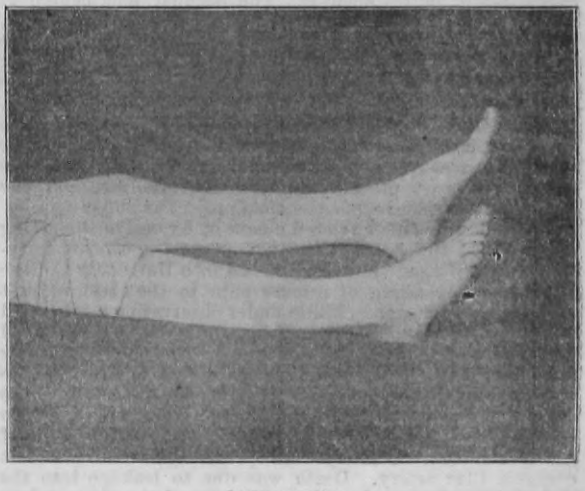


FIG. 1.

Before operation.

taken, the tibia being chiselled through at the point of bending—i.e., about one and a half inches below the tubercle. After the bone had been cut through to half its thickness it was easily broken and the limb returned to its normal position; the fibula did not require to be interfered

FIG. 2.

After operation.

with. The after progress was quite satisfactory, the wound running a normal course. Fig. 2 shows the present condition of the limb.

Remarks by Mr. BROWN.—Although I have from time to time met with instances of unusual growth in bone following upon injury I have never before seen a case in any way resembling the one above mentioned. The only solution which occurs to me is that the crush, which seems to have been very severe, has in some way so altered the nutrition of the tibia as to arrest development in its anterior planes, whilst it allowed the posterior half of the bone to continue growing. The fibula followed the new direction of the tibia. I should be glad to hear the opinion of others more skilled in the unravelling of pathological problems, of this deformity, which, so far as I can learn, has no parallel on record.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Intra-cardiac Thrombus.—Dissecting Aneurysm Rupturing into both Pleural Cavities.

A MEETING of this society was held on May 28th, the President, Dr. BUZZARD, being in the chair.

Dr. W. EWART and Dr. H. D. ROLLESTON described the details of a case in which a large Ante-mortem Thrombus was attached to the fossa ovalis in the left auricle, passing through the mitral valve, which was not contracted, into the left ventricle. The patient was a woman, forty-three years of age, who had had some acute chest trouble, probably pleuro-pneumonia, in February, 1896. Afterwards a slight systolic murmur with a snapping first sound was noticed. There was no knowledge as to the physical signs before the illness. After a time a presystolic murmur developed. The symptoms were those of mitral stenosis with failure of compensation. There were many periods of improvement followed by relapses. Later she became dropsical and the abdomen had to be tapped. She died ultimately rather suddenly with symptoms of pulmonary apoplexy. At the necropsy the viscera showed the usual changes met with in cases of advanced mitral disease. The heart itself weighed 19 oz., and was generally dilated, with hypertrophy of its walls. A firm, smooth, dark hourglass-shaped thrombus was found firmly attached to the lower posterior part of the foramen ovale, passing into the left ventricle, with a constriction at the mitral orifice, which was otherwise healthy. There were no adhesions between the flaps of the valve and the thrombus. Examination of the thrombus showed that it was old internally, and that recent clot had been added to it lately. The clinical interest of this rare case lay in the fact that the symptoms and signs were exactly those of mitral obstruction, which, indeed, existed, although there was no actual disease of the mitral cusps.—Dr. KINGSTON FOWLER referred to a case formerly under his care, which was reported by Dr. Voelcker in the Transactions of the Pathological Society for 1893, in which he noted that the cardiac rhythm was suggestive of mitral stenosis. The peculiar lengthening of the systole was one sign and the snapping first sound another. The case altogether had a very strong resemblance to the one described in the paper. He commented on the fact that there was a cavity in the centre of the thrombus, as was the case with the "ball clots" sometimes found in the heart. When met with in the auricle these clots usually arise between the strands of the musculi pectinati and in the ventricle between the chordæ tendineæ. In the early stage the central part probably underwent softening, and the cardiac contractions made the clots project as polypi.

Dr. BERTRAM HUNT related a case of extensive Dissecting Aneurysm of the Aorta. The patient was a woman, forty-three years of age, who was admitted into University College Hospital complaining of intense pain in the chest and left side of the abdomen. While under observation a left-sided hæmothorax developed, and thirty-three ounces of blood were removed by aspiration. A murmur was then heard over the spine. The patient remained in fair health for nine months, when she died suddenly. At the necropsy a large dissecting aneurysm was found, which commenced by an orifice in the inner coat of the aorta just below the origin of the left subclavian artery and opened again into the left common iliac artery. Death was due to leakage into the right lung and pleural cavity. The site of the old leak into the left pleura was closed by adhesions. Dr. Hunt had only been able to find ten recorded cases of dissecting aneurysms along which blood undoubtedly flowed. The clinical histories of these recorded cases are very similar and it might be possible to diagnose the condition during life. It was very interesting to note the fact that an aneurysm leaking into the pleura might close after aspiration of the effused blood.—Dr. DE HAVILLAND HALL said that in his experience, when a large aneurysm opened into a serous cavity there was usually a large sudden escape of blood, whereas when the aneurysm ruptured on to a mucous surface, the opening was valvular and blood escapes slowly.—Dr. KINGSTON FOWLER said that he had elsewhere drawn attention to this difference. The reason for the slow escape in this case was probably that the blood came from a dissecting aneurysm, and therefore not directly from the lumen of the aorta. He had placed a similar specimen in the museum of the Middlesex Hospital, in which there was also a small sac containing laminated clot opposite each intercostal artery.—Dr. ROLLESTON referred to two cases of hæmorrhage from the aorta into the pericardium, in which leakage occurred slowly. One was that of a man who was admitted with signs of pericarditis with much effusion. He died eight days later, when the pericardium was found to be distended with signs of pericarditis, and there was a leakage from an aortic aneurysm. The other case was one in which there was a very minute opening into the pericardium, which, however, contained twenty-five ounces of fluid. He remembered one case in which Dr. Dickinson diagnosed a dissecting aneurysm during life from the very acute pain which radiated along the arteries in both arms and legs.—Dr. EWART agreed that gradual leakage sometimes occurred in cases of rupture of an intra-pericardial aneurysm. He inquired where the puncture was made in the chest in this case. Was it possible that the fluid was really drawn off from the sub-pleural space, and not from the pleural cavity?—Dr. HUNT, in reply, said that it was obvious at the necropsy that blood had escaped by gradual leakage into the right pleura. With regard to the hæmorrhage into the left pleura, the needle was passed in deeply on several occasions, and there could be no doubt that the blood was in the pleural cavity. A microscopical examination of the wall of the aneurysm showed that it had burrowed down between the layers of the middle coat.

Annual Meeting.

The annual meeting for the election of office-bearers and general business was then held.

The report of the council showed that the society was in a prosperous condition both as regards accession of new members and an increased balance at the bank.

On the motion of Dr. DE HAVILLAND HALL, seconded by Mr. A. E. BARKER, an enthusiastic vote of thanks was passed to Dr. Buzzard, the retiring President, for his invariable tact, kindness, and courtesy in the chair.

Dr. BUZZARD, in reply, congratulated the society on its flourishing condition, and said that his work as President had been unalloyed pleasure.

The usual votes of thanks were passed to retiring members of council and a number of alterations in the wording of the rules to bring them into harmony with the modern procedure at the meetings were unanimously adopted.

The following gentlemen were elected to hold office during the coming session:—President: Mr. John Langton. Vice-presidents: Dr. Thomas Barlow, Dr. James Frederic Goodhart, Dr. Leonard William Sedgwick, Mr. William Henry Bennett, Mr. Rickman John Godlee, and Mr. William J. Walsham. Treasurer: Dr. William Miller Ord. Council: Dr. J. Ford Anderson, Dr. Arthur T. Davies, Dr. Sidney Martin, Dr. W. Julius Mickle, Dr. F. W. Mott, Dr. J. F. Payne, Dr. F. G. Penrose, Dr. J. J. Pringle, Dr. Seymour J. Sharkey, Dr. E. Markham Skerritt, Dr. W. Hale White, Mr. A. Pearce Gould, Mr. C. R. B. Keetley, Mr. C. B. Lockwood, Mr. Rushton Parker, Mr. Bilton Pollard, Mr. A. Q. Silcock, Mr. W. G. Spencer, Mr. T. P. Teale, and Mr. G. R. Turner. Honorary Secretaries: Mr. G. H. Makins and Dr. J. Kingston Fowler. Trustees: Mr. Christopher Heath, Dr. William Miller Ord, and Dr. J. Burdon Sanderson.

EPIDEMIOLOGICAL SOCIETY.

Seasonal Fluctuations of Epidemic Diseases.

A MEETING of this society was held on May 21st, Brigade-Surgeon-Lieutenant-Colonel J. LANE NOTTER, the President, being in the chair.

Dr. ANDREW DAVIDSON read a paper on the Seasonal Fluctuations of Epidemic Diseases. These fluctuations recurred constantly in each country, but varied in different climates and regions. Differences of season, however, frequently corresponded with like conditions of temperature and moisture of the soil, as was seen by the curves representing the single wave of cholera in temperate climates and the single or double curves observed in India, where it was endemic, depending on the period of the rainy season or monsoons. In seeking the causes of these seasonal variations the diseases due to facultative saprophytes existing in the

Hosted by Google

soil, such as cholera, enteric fever, malarial fevers, must be considered separately from small-pox and measles (obligatory carasites), which could be influenced by meteorological ponditions indirectly only, through the action of these on the resisting power or the habits and surroundings of the individual. Small-pox and measles had similar autumn, winter, spring, and summer curves; but when introduced into a highly susceptible community spread irrespectively of season until the susceptible material was exhausted. The heights of the spring and autumn curves of measles were reversed in the English and Scotch towns, as well as in other countries. But comparing compound curves of series of years with single ones, it was seen that in most years only one was strongly marked. Habits of life, overcrowding in cold or wet weather, and the aggregation of children in schools, were factors not to be ignored, and as regards the latter it was a common occurrence in Germany and Poland for an epidemic of measles to be restricted either to the Christian or to the Jewish population. Small-pox and measles had one or two annual curves in Baghdad, but were wholly absent during the absolutely rainless summer months. In London the death-rate from measles was highest in the second quarter in epidemic and in the fourth in non-epidemic years; but Dr. Davidson could not say whether the prevalence or the case mortality corresponded to the number of deaths, though the Hamburg returns showed such to be the case in that town. He would suggest in explanation of many of these phenomena that in non-epidemic periods only the more susceptible were attacked, and that the virus passing through such individuals gained in intensity and the disease spread further; but that when, as in epidemics the more resistent were attacked it became alternated in them until it died out. Why epidemics should usually occur in winter and spring it was not easy to say. In Europe, India, and America small-pox followed approximately the temperature curve, though it began to rise in winter when the temperature fell, but attained its maximum with the spring. The regular appearance of small-pox in the winter was ascribed by Flügge to the aggregation of persons indoors, the less frequent change of clothing, and the neglect of ablutions in cold weather; but this would not account for its maximum prevalence in early summer, and the conditions of domestic life in Europe did not apply to India where the same general curve was followed by the disease. It was easy to understand that facultative saprophytes multiplying in the soil were dependent on temperature and moisture, but these conditions could not directly affect those obligatory parasites whose soil was the living body; and these diseases followed their usual course irrespectively of climate and temperature. He had seen small-pox raging in Madagascar in 1868 when the temperature ranged between 90° and 100° F., and in 1870 it prevailed in the Hudson's Bay Territory with the thermometer at 4° F. below zero. All alleged relations between the prevalence of measles and the temperature were true of particular countries only, and therefore could only be accidental. Weather conditions tending to induce catarrhs of the pharyngeal and the respiratory mucous membranes could not fail to render the individual more susceptible to infection from diseases, such as scarlet fever, diphtheria, and measles, which were known to enter the body by these surfaces, and in like manner catarrh of the gastro-intestinal canal favoured the development of cholera and typhoid fever.

Dr. RANSOME showed numerous Charts of the Epidemiology of Manchester for Ten Years, which were practically the same as those for London. He fully agreed with Dr. Davidson's suggestions as to the influence of catarrhal affections in favouring infection by specific diseases, but he had observed also in 70 per cent. of outbreaks or exacerbations of scarlet fever that they coincided with a sudden fall of the barometer, suggestive of the escape of the poison with the ascent of sewer or infected ground air.

Dr. MCLEOD criticised the paper from an Indian standpoint, and the discussion was continued by Dr. PARSONS, Dr. NEWSHOLME, Dr. WILLOUGHBY, Dr. BULSTRODE, Dr. COUPLAND, and Mr. CHILD.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on May 27th, the President, Dr. MILSON, being in the chair.

Dr. LEONARD GUTHRIE showed a man, aged twenty-nine years, the subject of Muscular Dystrophy. There was marked atrophy of the quadriceps femoris on both sides, with pseudo-hypertrophy of the calf muscles. The infraspinati muscles were apparently enlarged, but not the deltoids or pectorales. The buttocks were wasted. Lordosis was slight. The gait and the method of rising to the erect position were characteristic of pseudo-hypertrophic paralysis. Swelling of the calf muscles and fatigue on exertion had been noted since early childhood. The symptoms had increased during the past three years. The patient's maternal grandfather and also an elder brother were said to be similarly affected.—Mr. JACKSON CLARKE observed that when lordosis was present in these cases it was the result of disturbance of balance rather than of muscular action.

Dr. KNOWSLEY SIBLEY showed a case of Phthisis associated with Rheumatism and Subcutaneous Abscesses, probably Tuberculous. The patient, a woman sixty-four years of age, had lost a sister from phthisis. The patient had never been very strong, but until last October, when both hands were attacked with rheumatism, she had never been laid up. Shortly after this a swelling appeared on the back of one hand and on the wrist of the other; these had persisted ever since. The patient had an irregular temperature, usually from 100° to 101° F. at night and subnormal in the morning; she had signs of old-standing tuberculous mischief at the right apex. Both hands were enlarged and all the fingers more or less stiff and painful; there were considerable thickening and grating about both the wrist-joints. There was a swelling about the size of a walnut over the dorsum of the left hand and another rather larger over the ulnar surface of the right wrist. These swellings were soft, fluctuating, and not tender. The contents, drawn off with a hypodermic syringe, consisted of clear pus. A trace of albumin was present in the urine. It was unusual that a patient suffering from chronic phthisis should late in life be attacked with a subacute form of rheumatism, followed by what appeared to be subcutaneous abscesses probably of a tuberculous nature. Dr. Sibley did not consider the whole process to be tuberculous, as there were distinct thickening and stiffness of the individual finger-joints apart from the disease of the wrist-joints. The patient had considerably improved since she was admitted into the North-West London Hospital and had undergone treatment by the Tallerman-Sheffield hot-air baths.—Mr. RAYMOND JOHNSON was inclined to regard the affection of the wrist-joints as tuberculous, and believed the superficial abscesses over the joints to have a deep origin. He referred to the fact that tuberculous disease of the wrist is usually met with in adults, and that probably it is more commonly associated with tuberculous disease of the lungs than is the case with the other large joints.—Dr. ALFRED EDDOWES said that it would not surprise him if such a condition of joints proved to be due to the tubercle bacillus, as that organism seemed to produce lesions varying greatly in appearance according to the position of the part and nature of the tissue attacked.

Dr. EDDOWES showed a case of Lichen Simplex Chronicus in which the lesion had existed for many years without improvement. He strongly advocated the employment of Unna's compound mercurial plasters, especially Nos. 16 and 88, for this rebellious disease. He had several such cases under his care and all had progressed as favourably as the patient shown, who was nearly cured. The treatment was simple, cleanly, and highly satisfactory to the patients. Dr. Eddowes also showed a patient suffering from Psoriasis Circinata in its most typical form.

BOMBAY MEDICAL AND PHYSICAL SOCIETY.

Dengue Fever.—The Pneumonia Type of Plague.

A MEETING of this society was held in the Durbar Room, Town Hall, Bombay, on April 2nd, Brigade Surgeon-Lieutenant-Colonel J. ARNOTT being in the chair.

Staff-Surgeon P. W. BASSETT-SMITH, R.N., read a paper on Dengue Fever in Bombay, making special reference to a frequently observed mild form which is characterised by a very slight degree of pain in the bones and muscles, and has led to great difficulty in the diagnosis. The earliest accounts

Hosted by Google

of dengue appeared in 1779, when it prevailed in Batavia and Egypt; it then spread to Zanzibar and the west coast of India, and in 1818 to America. In 1824–28 it was epidemic on the east side of India, spreading to Burma on the one side and to Gujerat on the other. Since then there have been many epidemics in both hemispheres. Dr. Sandwith, of Cairo, states that it is met with in a sporadic form in Egypt every year. In 1887 the rash was a very marked feature, suggesting that the disease was scarlet fever, and in 1896 some called it rötheln. The principal symptoms observed in Bombay have been a rapid onset of fever lasting three or four days, with a more or less perfect remission, then a secondary and shorter fever, followed by a period of two or three days with a subnormal temperature. At the same time there are severe frontal headache, pains in the back and thighs, and in a certain number of cases an eruption either with the primary or secondary fever or with both, generally of a very evanescent character. The attack is sometimes ushered in by slight shivers, always with intense headache. The temperature generally rises suddenly to between 102° and 104° F. on the first evening; it may remain up for two or three days, showing slight evening exacerbations, but more frequently there is a steady fall, taking two or three days to reach normal, and the patient then feels almost well. After a very short interval, generally on the fifth day, the secondary fever comes on, the temperature sometimes rapidly running up as high as in the primary. The subnormal period is always present. Rigors and severe sweats were never noticed. The headache, pain in the eyeballs, and backache were always very marked, but there was never any "break-bone" pain or severe pain in the joints. In the epidemic of July and August, 1896, an eruption very seldom appeared, but it occurred in about half the cases in the epidemics of December, 1896, and January, 1897, being then nearly always of a distinct scarlatiniform character, and the favourite seats being first on the elbows, the outer sides of the forearms and the front of the thighs, particularly over the knees. Generally it was very slight, and lasted often only a few hours. There was never any sore-throat or coryza. No enlarged glands were found anywhere, and beyond the anæmia and debility there were no consequences. The prognosis was good; each case lasted from one week to ten days, with one week's convalescence or less. Quinine was quite useless.

Surgeon-Captain L. F. CHILDE read a paper on the Pneumonia Type of Plague. He said that the increased death-rate in Bombay due to plague was accompanied by a large and unexplained increase assigned to remittent fever and respiratory diseases, a coincidence which induced him to examine the bodies of all hospital patients who had died from fever, pneumonia, or any acute illness, to see if there were evidences that any of them had really died from plague. He found twelve cases (the first of them in the end of December) in which during life all the symptoms pointed to disease of the lungs, and in which there were no evidences of glandular enlargement, whilst after death there was clear proof of enormous growth of plague bacilli in the lungs and of only very slight growth in the lymphatic glands. Surgeon-Major Manser was suddenly taken ill on Jan. 2nd, the disease assumed this form, and he died on Jan. 6th; he had no glandular enlargement or pain in the glands anywhere, but his sputum was seen with the microscope to be full of plague bacilli, and pure cultures were obtained from it.

THE MIDWIVES REGISTRATION BILL.—On Tuesday, May 25th, Lady Balfour of Burleigh presided over a meeting at the parish room, Kensington, in support of the above Bill. The Hon. A. de Tatton Egerton, who has charge of the Bill in the House of Commons, gave an account of its position there, and alluded favourably to a proposal made by Sir J. Blundell Maple as meeting one of the chief objections of the medical profession. This proposal was that every midwife or every person attending a confinement should within twenty-four hours notify to the district sanitary officer or officer of health that a confinement had taken place, and that such officer or medical practitioner appointed by him should visit the place, see that everything had been properly conducted, and receive a fee of 2*s.* 6*d.* for a distance not exceeding three miles. Mr. Egerton advocated the adoption of the proposal as being likely to overcome a large amount of objection to the Bill. Dr. Cullingworth also urged the acceptance of Sir J. Blundell Maple's suggestion.

Reviews and Notices of Books.

Diphtheria and Antitoxin. By NESTOR TIRARD, M.D., F.R.C.P. Lond. London: Longmans, Green, and Co. 1897. Price 7*s.* 6*d.*

THE undesirable prominence which has been gained by diphtheria within recent times, the regrettable mortality which it causes, the difficulty which seems to be confronted in the attempts to control its spread, and the numberless expedients which have been had recourse to for its treatment render it one of the most important subjects for investigation at the present day. Although its dependence upon a specific microbe has been established the conditions of its fateful diffusion amongst the child community are still to a large extent veiled in obscurity; for unhappily its recognition as a highly infectious disease does not explain all the facts of its dissemination, and the conditions under which it arises are so varied as almost to defy generalisation. It is, therefore, with pleasure that we welcome a monograph of the character of the one before us. Dr. Tirard writes with a commendable restraint upon the problems that surround the etiology of this dread disease, but gives wise counsel as to the lines upon which prophylaxis should be pursued. His experience of the disease in the wards of the Evelina Hospital has enabled him to give a lucid and thoroughly scientific account of the symptoms and complications which cannot fail to be of service to the practitioner. The work, however, lacks in completeness, as it does not embrace any study of the pathology and morbid anatomy of diphtheria. Its standpoint is almost purely the clinical one; yet, perhaps, for its purpose it is better that this should be so. It is instructive to note that Dr. Tirard does not lay much stress upon the symptom of albuminuria, which he, like Henoch, finds to be present in about one-half of the cases. He sees no cause for anxiety in the appearance of this symptom unless the albumin "exceed 30 per cent." (p. 17)—surely a very large amount—and he finds no ground for the belief that the kidneys are permanently damaged. At the same time if albuminuria is not as a rule a sign of severity it must indicate that the toxin has been absorbed into the circulation, and its early appearance must warrant the belief that this absorption occurs too soon to hold out much hope of arresting the disease by purely local treatment. Among special phenomena of the disease attention is drawn to the disproportionate rapidity of the pulse (another evidence of the early action of the virus) and to the marked pallor of the skin. The distinguishing features of the pharyngeal, laryngeal, and malignant forms are well brought out. An excellent account is given of diphtherial paralysis, and it may be noted that the author thinks that in cases of paralysis of the diaphragm death more often occurs from cardiac failure or secondary lung inflammation than from asphyxia due directly to the paralysis of the respiratory muscles. There is, we think, some ground for this statement, which, of course, does not apply to all such cases. Chapters on diagnosis and prognosis follow, whilst the subject of treatment is dealt with under the heads of hygienic, constitutional, local, intubation, tracheotomy, and, finally, of antitoxin serum. It is interesting to learn that at the Evelina Hospital intubation is now being so much practised and with such success. As regards the value of antitoxic serum Dr. Tirard's experience serves to confirm that of others, both as to its efficacy and as to the great importance of its early administration. The work is furnished with the details of many illustrative cases, and it is one which we can heartily commend to the profession as

Hosted by Google

constituting a faithful record of experience and containing much that is of real practical value.

Text-book of Forensic Medicine and Toxicology. By ARTHUR P. LUFF, M.D. Lond., B.Sc., &c., Lecturer on Medical Jurisprudence and Toxicology in St. Mary's Hospital, Examiner in Forensic Medicine in the University of London, Official Analyst to the Home Office. In 2 vols. Pp. 760. London and New York: Longmans, Green, and Co. 1895.

THIS is one of the best works on forensic medicine. The section on Toxicology, as would be expected from Dr. Luff's experience as analyst, teacher, and examiner, is of great excellence. The description of the various steps for the identification of poisons is lucid, concise, and accurate, contrasting strongly with the discursive method adopted in some text-books. The reader is not left in doubt as to the value of observations and experiments. In addition to the usual list of poisons we find a series of toxic agents introduced for discussion. Amongst these may be mentioned sulphonal, duboisine, gelsemium, jaborandi, antifebrin, exalgin, antipyrin, resorcin, salol, paraldehyde, &c.

The chapter on Criminal Abortion is well written. The method of removing the uterus might with advantage have been given in more detail, and a fuller description of the character of instrumental wounds, especially with regard to their probable age, would have been acceptable. The subject of Animal Alkaloids is handled with singular tact—a better account of a difficult problem in so short a space it would be difficult to conceive.

It is unnecessary to review in detail all the sections of the work. Taking it all in all, we are of opinion that no better exposition is within the reach of the student and practitioner. The type is clear and bold and the illustrations well executed. In a future edition we should like to see a separate index to each volume.

Practical Handbook of the Diseases of the Eye. By D. CHALMERS WATSON, M.B., C.M. Edin., Ophthalmic Surgeon to the Marshall-street Dispensary, Edinburgh. Pp. 248, with 9 Coloured Illustrations and 24 Figures in the Text. Edinburgh: W. F. Clay. 1897. Crown 8vo. Price 4*s.* 6*d.*

IN this little manual for the student and practitioner the principal forms of ophthalmic disease are briefly and dogmatically given under the heads of Causes, Symptoms, Prognosis, Result, and Treatment. The author has had considerable experience, and but little fault can be found in regard to the accuracy of his facts, which, perhaps, is the essential point in a work of this kind. At the same time, it must be acknowledged that the account of each disease is a trifle bald and dry and offers little temptation to the student to read the next page.

The two introductory chapters are devoted to the examination and therapeutics of the eye. In making a few comments that have suggested themselves to us in perusing this little book we should be disposed in the first place to dispute the statement made on p. 22 by the author, that in blepharitis ciliaris the health is always low, and he does not mention among the causes of that condition hypermetropia, which is of common occurrence. Tarsal cysts are not always cured by everting the lid, dividing, and scooping out the contents; certain forms are more perfectly removed by dividing the skin and excising the cyst completely.

The operation of slitting up the canaliculus is spoken of too lightly; it is here put in the first place, and the student might easily be induced to undertake it in slight cases where the extraction of a tooth, attention to the nasal mucous membrane, the use of probes, and a lotion might effect a cure. The operation, as most men of experience know, not unfrequently leaves the patient in worse plight than he was before, simple as it may seem. Under the head of Diphtheritic Conjunctivitis chlorine water might have been mentioned as a highly effective remedy.

Dr. Chalmers Watson has no hesitation in admitting the presence of radiating dilator muscular fibres supplied by the sympathetic nerve in the iris. His view is probably correct, but the radiating fibres are uncommonly difficult to demonstrate.

A few more examples of the mode of correcting errors of refraction might have been given with advantage. None is given of mixed astigmatism, which, however, the author may think can hardly be undertaken by those who are likely to use his work. He lays down the following rules in regard to the use of glasses in myopia. "Before full growth correcting glasses should be worn for near work....After full growth, twenty-two or so, there is not the same necessity for wearing full strength for reading."

The account of each affection given is good as far as it goes, but this is not always far enough; if we take Pterygion as an example we find the treatment recommended to be—"(*a*) as a rule, leave alone; (*b*) removal under cocaine may be had recourse to in cases when the patient is young and the disfigurement is marked," but some account of the mode of dealing with the apex of the growth should have been given, otherwise the affection returns. The book will prove of most service to those who are attending the practice of an ophthalmic institution and who are about to present themselves for an examination. The chromo-lithographs are fairly done, and though they do not pretend to be finished drawings the diseases they are intended to illustrate are easily recognisable.

Functional Disorders of the Nervous System in Women. By T. J. MCGILLICUDDY, A.M., M.D., Consulting Physician to the Italian Hospital, New York, &c. Illustrated by 45 Wood Engravings and 2 Chromo-lithographic Plates. London: Baillière, Tindall, and Cox. 1896. Price 12*s.* 6*d.*

THE author considers that the attention of the profession has been confined of late years too exclusively to surgical gynæcology and to diseases with marked pathological changes. His intention in the work before us has been to draw attention to a class of affections which are more frequently seen in private than in hospital practice, and are not so minutely described as the important organic diseases and surgical affections. To write a good book on the functional derangements of the nervous system in women is a work of considerable difficulty; but we think that, on the whole, the author has succeeded in his task. The book is clearly written, and contains much that should prove useful both to the general practitioner and to the obstetrician. We may quote the following as illustrative of the author's standpoint:—

"For example, if the confiding and unsuspecting patient with a run-down constitution—the result of anxiety, bad air, and a worse diet, with a headache and some abdominal or uterine symptoms—strays into the office of an enthusiast in ocular tenotomy he will probably want to relieve her distress by dividing the rectus muscle for eye-strain. If, however, as is more likely, she applies to a surgical gynæcologist of a certain class, a symptomatic uterine catarrh, an inoffending laceration, or a harmless, retiring, cystic ovary will be pounced upon by this enlightened specialist and receive vigorous treatment, and if he does not always sterilise carefully his instruments he usually succeeds in sterilising the patient."

After this we are disappointed to see it stated at the end of the chapter on Therapeutics that dilatation for stenosis and flexion of the uterus may be necessary in many neurasthenic and hysterical women, and that "stenosis is very frequently at the internal os and is caused by flexion of the neck on the body." The author makes the old mistake of

Hosted by Google

comparing the thick-walled uterus to a piece of relatively thin-walled indiarubber tubing. In many ways the advice given as to general treatment seems to us to be excellent.

Materia Medica, Pharmacy, Pharmacology, and Therapeutics. By W. HALE WHITE, M.D., F.R.C.P. Lond. Second Edition. London: J. and A. Churchill. 1897.

AT the rate at which new drugs are now introduced to the notice of the medical profession it would seem that a new edition of a book on Materia Medica would have to be a frequent occurrence. Fortunately, however, for those who compile text-books on this subject, and still more fortunately for those who have to learn them, the authorities put a merciful limit to the subject by only making those drugs "official" which have substantially proved their usefulness in the healing art. In practice, however, no hard and fast line can be drawn, and drugs which are "non-official" are being every day used, and while the student working for examination only concerns himself with the official drugs, the practitioner takes a wider view and likes to know something of those which, though useful, have at present failed to gain the distinction of being included in the Pharmacopœia. Dr. Hale White has in this edition met the desires of both these classes of readers, for he has removed the principal non-official drugs from an appendix and has placed them together with the other drugs in their proper places according to their actions. The first part of the book is set aside for definitions and explanations of the physiological actions of drugs, and the drugs are grouped according to their various actions on the different systems of the body. The rest of the book is devoted to the different drugs in detail, and at the end is an appendix containing the pharmacopœal vegetable drugs arranged according to their natural orders. The work has already proved a useful text-book for both students and practitioners, and in the present edition it has been brought up to date and will no doubt continue to be widely read.

LIBRARY TABLE.

Formulaire Aide-Mémoire de la Faculté de Médecine et des Médecins des Hôpitaux de Paris. (Selected Prescriptions and Hints, Medical and Surgical.) Par le Docteur FERNAND ROUX. Quatrième Édition. Paris: G. Steinheil. 1896. Pp. 423. Price 3 francs.—*Nouvelles Formules d'Oculistique. (Prescriptions for Use in Ophthalmic Practice.)* Par le Docteur de BOURGON. Paris: Société d'Éditions Scientifiques. Pp. 299. Price 5 francs.—*Formulaire des Médications Nouvelles. (Modern Methods of Treatment.)* Par le Docteur H. GILLET. Paris: J. B. Baillière et Fils. 1896. Pp. 252. Price 3 francs.—*Formulaire des Médicaments Nouveaux pour 1897. (Recent Additions to the Materia Medica.)* Par H. BOCQUILLON-LIMOUSIN. Paris: J. B. Baillière et Fils. 1897. Pp. 308. Price 3 francs.—These little books will be found useful by all who desire to know something of the special features of French medical practice; they also contain much information in reference to many therapeutic novelties. The one first mentioned is of course not an official publication of the Faculty of Medicine; it is a kind of "prescriber's handbook," in which the diseases or other morbid conditions are arranged alphabetically, beginning with "Abcès" and ending with "Zona"; on an average two or three fully written-out prescriptions are given under each heading. The second contains a tolerably full account of the various medicinal substances used in ophthalmic practice. With respect to the third, mention may be made of the sections on asepsis and antiseptic methods, on various kinds of baths, on a large number of antitoxin serums, on animal extracts, on intravenous and subcutaneous injections of many kinds, &c. The fourth gives an account of several hundreds of new or comparatively new drugs, preparations, and medicinal plants, including the following bactericides and antiseptics:—Actol, antinosine, ferrostyptine, glutol, iodoformine (not the same as iodoform), itrol, orphol, quinosol, sanoforme, and xéroforme.

Annuaire des Eaux Minérales, Stations Climatiques, et Sanatoria de la France et de l'Étranger. (Guide to the Mineral Springs and Health Resorts of France and several other Countries.) Paris: The Publishing Office of *La Gazette des Eaux*. 1897. Pp. 272. Price 1 franc 50 cents.—This useful little book, which is now in its thirty-ninth year of issue, is written principally for the benefit of visitors to the numerous places in France where treatment by mineral water is carried out. There is also a large amount of concisely expressed information concerning the mineral springs in other continental countries, and those in England are not neglected.

JOURNALS AND REVIEWS.

The Practitioner.—We heartily congratulate Mr. Malcolm Morris on the enterprise by which he has been enabled to present the readers of his journal with a double number in special commemoration of Queen Victoria's Diamond Jubilee. He has been fortunate to secure as contributors writers whose special knowledge well entitles them to fill the *rôle* of historians. Thus Dr. Wilks gives under the title "Fifty Years Ago" a most interesting account of the state of hospital management, medical education, and practice in these days. No one can read these personal reminiscences without being vividly impressed with the enormous advance which has been made in these respects during this time. To Sir Dyce Duckworth is assigned the task of recounting in detail the Advance in the Principles and Practice of Medicine during the Sixty Years of the Reign of Queen Victoria, and it is needless to say that his survey is accurate and complete. Sir W. Broadbent traces the remarkable growth of knowledge in the domain of Nervous Diseases; Sir James Crichton-Browne that of Psychological Medicine. Mr. F. Treves writes on the Progress of Surgery, and Mr. Watson Cheyne on Wound Treatment during the Victorian Era. There are also articles by Dr. Champneys and Dr. Drummond Robinson on Midwifery and Gynæcology; by Mr. Henry Power on Special Branches of Medicine and Surgery; by Professor D. G. Hamilton on Pathology; by Dr. Sims Woodhead on the Birth and Development of Bacteriology; by Professor D. G. Leech on Therapeutics; by Dr. Edward Seaton on Public Preventive Medicine; and by Miss C. J. Wood on Nursing. An interesting feature of the number is the list of physicians and surgeons who have held Court appointments during the reign, special memoirs with portraits being given of Sir James Clark, Sir Charles Locock, Sir W. Jenner, and Sir James Reid.

The Cornhill for June contains several interesting papers. Lady Jane Ellice's Recollections of the Queen's Childhood are written by one who was Her Majesty's bridesmaid. The "Pages from a Private Diary" are witty and chatty as usual, while Cambridge men will read with especial interest Mr. Owen Seaman's verses on the recent development of the Women's Question at the university. The following argument for justice to women is worth quoting:—

> "It took a woman's tact to jog
> The Infant Don upon her knee;
> Nay, but for her the pedagogue
> Would be without a pedigree."

The Contemporary Review.—In a paper on Darwinism and Design Professor Schiller opens up a subject full of thought. Whilst accepting the interesting links in the story of evolution, first intelligibly put before the world by Charles Darwin, he is not satisfied that natural selection is sufficient to account for the whole design in creation. The question he

Hosted by Google

asks is, "What is the value of natural selection if it does not explain evolution completely?" Incomplete as the explanation offered by the Darwinian theory may be, there can be little doubt that evolution affords, as Professor Schiller admits, the most hopeful method of approaching the mystery of existence.

The Westminster Review.—None can doubt the importance of the question of food supply in time of war, and this, perhaps, is one of the most interesting subjects treated in the June number. Lieutenant-Colonel T. A. Le Mesurier deals with the subject, as might be expected, largely from a military aspect, but still he has an eye to the economics of the question. He points out that two-thirds of our annual consumption of farinaceous food and three-sevenths of our meat supply have to be imported from abroad. Worse still, 2,000,000 of acres of wheat land have during the last two decades been devoted to other uses. "More ships, more men, and more guns" are our only need, according to this writer, if we are to maintain the commercial supremacy we now enjoy and if we may hope to be able to import such supplies as may become an absolute necessity in time of war. He proposes further to redeem our agricultural shortcomings, by directing the labour at the disposal of our workhouses and prison establishments to the cultivation of the soil. For ourselves, we do not think we shall at any one time make enemies of every country in the world, especially as arbitration is beginning to appeal strongly to the nations as the only wise and rational method of settlement. Coupled with this assurance we may depend with some confidence on the resources of our colonies.

Analytical Records
FROM
THE LANCET LABORATORY.

SCOTCH WHISKY (THE SCOTSMAN BLEND).
(J. H. DEWAR, 47, ROSE-STREET, GLASGOW.)

THE following results of analysis of whiskies of varying ages are interesting in illustrating to some extent the influences of "keeping" upon the composition of spirits. Whisky six years old gave the following results: alcohol by weight 42·05 per cent., by volume 49·55 per cent., equal to proof spirit 86·84 per cent.; acidity reckoned as acetic acid, 0·036 per cent.; extractives, 0·65 per cent.; mineral matter, *nil*. Whisky, ten years old: alcohol by weight 42·05 per cent., by volume 49·55 per cent., equal to proof spirit 86·84 per cent.; acidity, 0·036 per cent.; extractives, 0·685 per cent.; mineral matter, *nil*. Whisky, fifteen years old: alcohol by weight 39·80 per cent., by volume 47·13 per cent., equal to proof spirit 82·59 per cent.; acidity, 0·036 per cent.; extractives, 0·815 per cent.; mineral matter, *nil*. It will be seen from these results that with increasing age, as might be anticipated, the amount of extractives increases. This is, of course, derived from storage in sherry casks which contain more or less resinous matter. There is practically no difference in the alcoholic strength between the five-year and ten-year old samples, but in the fifteen-year old sample the spirituous strength is decidedly lower, owing, doubtless, to the evaporation of spirit during storage in wood. To the taste all were satisfactorily mellow, the oldest sample being particularly mild and soft. These whiskies are evidently pure, well matured, and in excellent condition.

PREPARED COD LIVER.
(NORWEGIAN MEDICAL COD-LIVER COMPANY, CHRISTIANIA, NORWAY. AGENT: B. SCHUMACHER, 7 AND 8, IDOL-LANE, E.C.)

This production is the result of an improved process for the preservation of the liver of the fish in its entirety. The aim of the process is to prevent the oil in which the liver is boiled from mixing with the oil contained in the cells of the liver itself. When fresh liver is boiled in oil in the ordinary way the temperature attained brings about the rupture of the tissue of the liver, so that the oil of the liver mixes with and diffuses into the oil in which it is boiled. This is entirely obviated by boiling the liver in oil under a reduced pressure. The boiling point is correspondingly lowered, and the tissue of the liver is not burst. The preparation presents the characteristic taste of the fresh boiled liver. It is decidedly salt, but contains no objectionable preservatives. On ignition an abundant ash is obtained consisting entirely of common salt and soluble phosphates. The liver may be eaten as an agreeable and excellent substitute for caviare or as an adjunct partaken before a meal. It is very good when spread on bread, rusks, or toast. We can commend it because, being prepared with special precautions, its taste is delicate and its medicinal properties are preserved intact. It should prove an excellent nutritive and tonic.

KEROS FLUID BEEF.
(BOUILLON FLEET, LIMITED, WARNER-ROAD, CAMBERWELL, S.E.)

The following were the satisfactory results yielded by this preparation on analysis: water, 33·9 per cent; organic matters, 43·04 per cent.; mineral matter, 23·06 per cent. The organic matter contained 3·76 parts albumin (separated on boiling after slightly acidulating with a few drops of acetic acid), 25·64 peptonic matter, and 13·64 parts of beef extractives, including crystalline principles. From these results it is evident that the preparation possesses high nutritive power referable to the albumins and peptones, while the excellent proportion of meat extractives makes it of value as a stimulant and appetiser. The taste is good and commendably free from burnt flavour.

VIN KAFRA.
(THE MEAD MANUFACTURING CO., 156 AND 157, ALDERSGATE-STREET, E.C.)

Vin Kafra is described as a "tonic of tonics," which from the results of our examination we suppose is ascribed to the fact that it contains extractives identical with those of the kola nut. On suitable treatment the alkaloid caffeine was separated and identified. Further analysis gave the following results: alcohol by weight, 13·31 per cent.; by volume, 16·43 per cent., equal to proof spirit 28·78 per cent.; extractives, 10·05 per cent.; mineral matter, 0·036 per cent., consisting chiefly of the alkaline carbonates. Vin Kafra is a wine of the colour of sherry, but not quite clear, and possesses a peculiar nutty flavour. It may prove useful as an agreeable tonic and recuperative, but of its claims as an "anuretic," "diuretic," "aphrodisiac" we cannot speak, but are inclined to express on this score an opinion not in its favour. It is difficult to understand how a preparation can be at the same time "anuretic" and "diuretic."

KONIG'S ETHER.
(AGENTS: THOMAS CHRISTY AND CO., 25, LIME-STREET, E.C.)

The specific gravity of this liquid proved to be 0·6564, and on fractional distillation the bulk of it appeared to distil between 30° C. and 50° C., while portions remained boiling at between 60° C. and 70° C. These results are in accordance with what would be obtained with a mixture of petroleum ether, and ordinary methylated ether. The portion boiling between 40° and 60° smelt unmistakably of light naphtha or petroleum ether. The mixture is suggested for use in local anæsthesia. It appears to possess some advantage over pure ether, since while the evaporation is rapid the cold produced is more protracted. Good results are stated to have been obtained with it on the Continent, reports of which have been published in the German medical papers.

"CAMBRIDGE" SAUSAGES.
(J. A. RADCLIFFE AND CO., EXCELSIOR WORKS, HECKMONDWIKE.)

It is satisfactory to be able to state after both a chemical

Hosted by Google

and a microscopical examination that there is nothing mysterious in the composition of these useful articles of food. They are free from excess of bread, are well seasoned, and of excellent flavour. They are preserved with a trifling quantity of borax.

EIFFEL TOWER LEMONADE.
(G. FOSTER CLARK & CO., MAIDSTONE.)

Eiffel Tower lemonade consists of lemon-yellow crystals, smelling agreeably of the fragrant oil of lemon. On placing the crystals in water a yellow opalescent solution results, which in appearance is exactly like "lemon squash." The taste of the solution is agreeably and somewhat sharply acid. On shaking the opalescent liquid with ether clarification ensues and the ether on evaporation yields the essential oil of lemon. The preparation is genuine and affords a convenient means of preparing a very pleasant and wholesome beverage. There was no indication of metallic contamination.

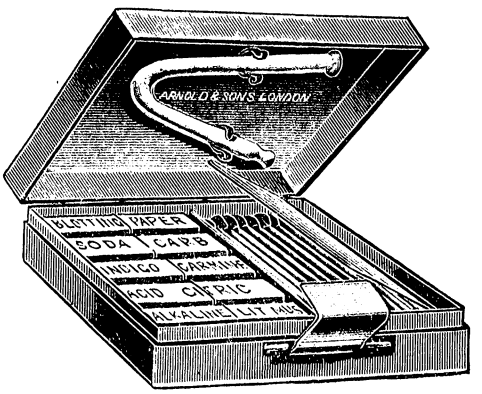
ZULANA PATENT FOOD.
(THE CORNILLA AFRICANA CO., DURBAN, NATAL. LONDON: J. HOWARTH 243, PENTONVILLE-ROAD, KING'S-CROSS.)

This prepared food presents no peculiar feature. It is evidently cooked and accordingly contains soluble starch and dextrine. The taste is biscuit-like and somewhat malty. The yield of mineral matter was 0·80 per cent. which contains a good proportion of soluble phosphate. The microscope showed starch cells identical in form with those of wheat flour.

New Inventions.

ASEPTIC MEMBRANE PERFORATOR.

THERE are times at a confinement when one's finger nails cannot readily rupture the membranes and when one needs a probe or a hairpin with which to perforate them. One cannot always procure a clean hairpin, and in any case the rendering it aseptic wastes time and causes trouble, particularly if one insists on boiling it. Then, again, certain patients are apt to think the use of a hairpin in labour somewhat clumsy, and may even resent it. For the ordinary hairpin this clean perforator will be found a good substitute. It is made of celluloid, or, if desired, of glass or vulcanite, and it is kept in a 1 in 1000 solution of perchloride of mercury in a little glass-stoppered bottle without a collar. Being small it can be used without fuss or the patient's knowledge. It was shown before the Leeds and West Riding Medico-Chirurgical Society on Nov. 6th, 1896. It is made by Messrs. Reynolds and Branson, of Leeds.



½ SIZE

HERBERT J. ROBSON, L.R.C.P. Edin., M.R.C.S.Eng.
Leeds.

MINIATURE POCKET URINARY TEST CASE.

THIS case is intended for qualitative urinary analysis. It is designed to supply especially a rapid, simple, and satisfactory method of testing for albumin by boiling. The leading feature of the case is the V-shaped test-tube, which, from its shape, allows of one portion of the urine being boiled, and then of being closely compared with the unboiled portion. About half a drachm of urine only is required for the test, and it takes, literally, only a few seconds. To use the test-tube one limb is immersed in the urine and the V is then held upright, the liquid falling to the same level in the two limbs. After drying the tube on the blotting-paper provided for the purpose the heat of a burning match is applied near the surface of the fluid in the limb with the contraction, the tube being held by its other limb. The contraction tends to prevent boiling over, and the test can be applied several times to successive portions of the fluid with the same match. The boiled and the unboiled portions of the urine may, of course, be readily compared by holding the tube against the coat sleeve or other black surface. Papers soaked in citric acid or carbonate of soda papers accompany the tube for the purpose of neutralising the urine or for acidulating it after boiling. Indigo-carmine papers are also included for testing for glucose, the test consisting in the production of colours from violet to yellow, according to the amount of sugar present. Dr. Oliver directs that the test-tube be filled with ordinary water boiled with a part of the indigo-carmine test

paper immersed in it, and finally cleared of any turbidity by means of the carbonate of soda paper. A minute portion of the suspected urine is then added to the water and the whole is again boiled for a few seconds. It should be held against a white background. The case is made by Messrs. Arnold and Sons, of West Smithfield, E.C.

GLASGOW UNIVERSITY CLUB, LONDON.

THE annual general meeting of this club was held on the 28th ult., in the Café Royal, Regent-street, W. Lord Kelvin was re-elected President and presided over the dinner, which was attended by about 100 members and their friends. Lord Lister was a guest of the club, and among others present were Lord Shand, Dr. Farquharson, M.P., the Rev. Dr. M'Ewan, Professor J. M. Thomson, F.C.S., Professor G. G. Ramsay, LL.D., Professor W. Paton Ker, Professor Gairdner, M.D. Edin., LL.D., Messrs. M'Vicar Anderson, J. R. M'Ilraith, M.A., LL.B., and J. M. Dodds, and Dr. D. C. M'Vail, Dr. Norman Kerr, Dr. N. M. MacLehose, Dr. Forsyth, Dr. G. A. Heron, Dr. Anderson, &c. Lord Watson and Professor Dewar sent apologies for absence. After the toast of "The Queen" had been proposed by the President and loyally responded to, Professor W. Paton Ker proposed the toast, "Our Alma Mater and the Club," coupling it with the names of Professor Ramsay, of Glasgow, and Professor J. Miller Thomson, lately treasurer of the club, whom he congratulated on having recently become a Fellow of the Royal Society. Professor G. G. Ramsay, in reply, said he was glad the toast had been made to include past and present members of the University. It was a great pleasure to come to these dinners and meet old friends, and Glasgow students might well be proud of the tie which bound them to their Alma Mater. Lord Lister, who was present, was really a Glasgow man, and began his great work in Glasgow where he himself had been a student at the famous little room at the back of Newton-place. Professor J. Miller Thomson replied on behalf of the club, after which Lord Kelvin proposed the health of the guest of the evening—Lord Lister. The noble lord, he said, was born not far from London, but spent twenty-four years in Scotland. He entered on his professional career at Glasgow, where he was a professor of surgery in 1861. Then came Pasteur's researches, and the first man in this country to embark on the new study was Lister. And the result of the new mode of treatment which he advocated in consequence had been the salvation of thousands of lives. London had him now, but Glasgow would never lose him.

Lord Lister, in reply, said that he had spent the happiest years of his life at Glasgow, while it was there that he met with his earliest successes, when wonderful discoveries followed one another almost daily.

The remaining toasts were "The Guests," proposed by Lord Shand and replied to by the Master of Peterhouse, Cambridge, and "The Chairman," proposed by Professor Gairdner and replied to by the President. Before the company parted Mr. Nicholl sang "Annie Laurie" and other songs.

THE LANCET.

LONDON: SATURDAY, JUNE 5, 1897.

THE General Medical Council rose on Monday last, having sat for six days and deliberated on many subjects of interest to the profession. As we have had occasion to point out before, the coöperation of the Privy Council with the General Medical Council has to be reckoned with. This imposes more carefulness on the part of the General Medical Council in coming to judgment on certain questions and in the form in which it gives force or expression to those judgments.

Three questions which came before the General Medical Council this session emphasised more or less this association of the Privy Council with the medical body—viz., the appointment of surgical examiners to the Apothecaries' Society of Ireland, the consideration of the Midwives Bill, and the disciplinary functions of the qualifying bodies. The General Medical Council bowed, of course, to the direction of the Privy Council in the matter of appointing surgical examiners to the Apothecaries' Society of Ireland. Sir DYCE DUCKWORTH lamented that the Privy Council had imposed this duty on the General Medical Council, and was disposed to complain that the usefulness and authority of the inferior tribunal would be impaired. But we believe that it will be found that the General Medical Council by its compliance has in no way damaged its real usefulness. It has only taken a step for the results of which the Privy Council is solely responsible, while it has simultaneously vindicated its authority in carrying out the direction of the Privy Council, for in appointing surgical examiners it did not appoint the two gentlemen suggested in the letter of the secretary of the Society of Apothecaries of Ireland but two other gentlemen, doubtless equally qualified to hold the posts. The representative of the Society on the Council, Mr. TICHBORNE, showed his good sense in at once agreeing to the gentlemen selected by the committee of the Council to which the matter had been referred.

In regard to the Midwives Bill, the Privy Council is already in possession of the views of the General Medical Council as to the general principles to be observed in such a measure. But their Lordships, in response to an invitation, courteously desired its opinion on the Bill now before Parliament, anticipating that the Bill may be brought forward quite soon. It will be a serious thing for the General Medical Council if a Midwives Bill is annually referred to it for consideration. On the last occasion such a Bill was referred to a committee and then fully and at length debated in conclave, while the present Bill is not essentially different. It is to be referred in the same way and to go through the same process, which is satisfactory, as the Council now contains two new members representing the profession directly, whose views should be heard. But why the General Medical Council, having asked the Privy Council if an opinion would be of any use to them at once, and having received a reply in the affirmative, elected to delay giving the opinion we cannot exactly understand. For the mere sake of protecting the General Medical Council from an annual demand upon its time expedition would have been desirable. The views of the new members could have been elicited without delay. The third subject, showing the association of the Privy Council with the General Medical Council, was that of the disciplinary functions of the bodies which grant degrees and diplomas. The Privy Council has of late years strengthened the ethical powers of one of the corporations, and in a letter to the General Medical Council, alluded to in the recent debates, it has expressed its willingness to consider applications from chartered medical bodies for supplemental charters, and has pointed out ways in which universities and other licensing bodies could proceed for similar purposes. It was sought in the recent debate to make it appear that the Privy Council would only grant such supplemental powers within very strict limits. This is an assumption that might be disproved by further appeals by the bodies to the Privy Council, which is in advance of some universities in desiring greater disciplinary powers where the responsibility of granting degrees is present.

Advantage was very properly taken of the sitting of the Council to bring its influence to bear on pending legislation. A committee was appointed, with Dr. THORNE THORNE as its chairman, to consider the grave faults of the proposals now before Parliament in connexion with the Public Health Bill of Scotland, proposals that are inconsistent with the spirit of all recent legislation and of the rules of the General Medical Council in reference to the high qualifications of medical officers of health. All our readers know our views upon certain amendments to this Bill. The committee's report was adopted and ordered to be forwarded to the Secretary for Scotland and the Lord Advocate, and also to members of the Committee on Law. In like manner it was sought to procure the insertion of a clause in the Metropolitan Police Act to rectify the fault by which, in the Metropolitan area, fines which are imposed under the Medical Acts, which should go to defray expenses of prosecutions, are used to pay the expenses of police courts. Altogether the Council has had great public questions under consideration, and has taken for the most part a sensible course in regard to them. It is in the true interest of the profession that the Council should recognise the importance of questions affecting public health and professional morals, in which also the public is very deeply concerned.

THE PRINCE OF WALES, accompanied by the PRINCESS OF WALES and PRINCESS VICTORIA OF WALES, visited the City-road on May 28th for the purpose of laying the foundation-stone of the new building of the Royal London Ophthalmic Hospital. The PRINCE OF WALES made an interesting speech on the occasion, in which he adverted to the fact that this hospital was founded in 1804 by some gentlemen whose sympathies were aroused by the terrible sufferings of men of the Army and Navy invalided from the force under Sir RALPH ABERCROMBY during the Egyptian Campaign. It is a significant fact, said His Royal Highness, that while in this campaign in the early part of the century ophthalmia

Hosted by Google

produced great ravages—out of a regiment of 700 men there were 636 cases, of whom 40 became blind of one eye and 50 blind of both—in the Egyptian Expedition of 1882, though there were 1800 cases of ophthalmia after Tel-el-Kebir, not one man lost his sight. This, added the PRINCE OF WALES, was entirely due to the excellent precautions taken.

The facts connected with the history of contagious ophthalmia in the British Army are interesting and instructive. About the best practical illustration that can be furnished of what has been accomplished by the sanitary changes that have taken place in the Army since the Crimean War is the great difference that has taken place in the prevalence of ophthalmia. In the past this disease was for years a scourge of the Army; invalids suffering from the intractable effects of ophthalmia were to be found at most large military hospitals; outbreaks of ophthalmia were common at many of our Mediterranean and foreign stations, and unfortunate soldiers invalided and pensioned from the service on account of it were to be frequently encountered in civil life. But old soldiers with contracted brows, swollen eyelids, and blinking eyes—telling their tale of pain, intolerance of light, and defective vision—are no longer to be seen. Contagious ophthalmia was held by some to have been introduced into Europe in the beginning of the present century by the return of the French and British armies from Egypt. Be this as it may, there was a good deal of this distressing affection in European armies long after that date, and in 1858 the report of the "Congrès d'Ophthalmologie de Bruxelles" gave much information in regard to it. That it was a disease intimately associated in its earliest stages with follicular changes and the presence of so-called "sago grain" appearances in the palpebral conjunctiva soon attracted attention, and that these appearances, again, were associated with the unhygienic conditions to which people living in community were exposed was also soon recognised; indeed, some have even gone so far as to declare that the condition of the conjunctiva of the men of a regiment or of a large school affords a delicate test of their sanitary environment. In 1860 and 1861 two medical officers of our own army directed attention to the nature, causes, and prevalence of the disease in papers published respectively in *Beale's Archives* and the *Army Medical Reports*, and their observations were soon followed by those of others. The writers of the papers in question — Dr. JEFFERY MARSTON and Dr. PHILIP FRANK—not only went fully into the anatomical nature and pathological changes induced in the affected structures, but described the etiological conditions that gave rise to them; and the former subsequently prosecuted his inquiries in connexion with the late Sir WILLIAM BOWMAN at the Central London District Schools.

The sanitary report of the expedition to Egypt of 1882 contains some interesting observations on the subject of ophthalmia generally and on the disease as it appeared in the force taking part in that expedition. The appearance of the disease among our troops on that occasion gave rise, it will be remembered, to all kinds of gloomy prognostications, which were happily not fulfilled. Of the total number attacked, and of those invalided to this country during the Egyptian War of 1882, not a man, as the PRINCE of WALES said, lost his sight. The knowledge that then existed in regard to the causes of contagious ophthalmia and the way to prevent or limit its spread, together with the application of antiseptic methods of treating it, gave rise to the strikingly different results of the earlier Egyptian expedition under Sir RALPH ABERCROMBY and that of 1882 under Sir GARNET (now Lord) WOLSELEY. The medical officers of the latter expedition are to be congratulated on the results they obtained in this respect, as well as on the complete freedom of their patients from infective wound disease (almost unprecedented at that time in the annals of military surgery), which was due to the careful application of the principles of Listerism in the treatment of gunshot wounds.

IT seems evident that the public in Scotland are becoming alive to the serious nature of the "amendments" on the Public Health Bill to which we recently called attention.[1] The Chamber of Agriculture has dealt with the matter, and the leading newspapers have also pointed out the dangers likely to result from the dear and nasty system which has, unwittingly as we believe, been approved by the Grand Committee, and under which property of every sort would be open to attack as "injurious or dangerous to health" under a certificate granted by a sanitary inspector who himself is not required to possess any kind of knowledge on the subject. The General Medical Council, on the initiative of Dr. THORNE THORNE, has now also taken very satisfactory action in the matter, and a copy of the resolutions which it has unanimously passed is to be forwarded to the proper authorities.

A careful examination of the Bill reveals some extraordinary possibilities. Everyone now knows that it is proposed that whenever any individual, be he labourer or artisan or police constable, is appointed as a sanitary inspector, he is to be thereby endowed with the statutory right to certify what is dangerous or injurious to health; and on this certificate, without further evidence of any sort, the sanitary authority may proceed to a prosecution. This, however, is by no means all. Another clause of the Bill enacts that a sanitary authority may appoint any committee to take proceedings on its behalf. The same clause says that a quorum of two shall be sufficient for such a committee. Then the clause goes on to declare that this committee may itself delegate to any officer the duty of taking legal proceedings which has been already delegated to itself by the sanitary authority. Here, therefore, we may have first of all delegation by the sanitary authority to a committee; next, any two members constituting a quorum may delegate to the sanitary inspector the right to carry on prosecutions; and, finally, the sanitary inspector, acting under one clause, may thus certify to the same sanitary inspector acting under another clause that he ought forthwith to proceed against the owner, say, of a street of dwelling-houses, and that these proceedings ought to be taken before a court consisting of a single one of the two members (he being a magistrate or justice) who delegated to him this power of prosecution; and this court so constituted may forthwith decide that the dwelling-houses

[1] THE LANCET, May 8th and 15th, 1897.

Hosted by Google

in this street are unfit for human habitation, and from this decision there can be no appeal.

A few days ago it seemed possible that the Bill might get through the Grand Committee stage so quickly that the report stage in the House of Commons would be reached before Members of Parliament and the public had become alive to the possibilities opened up by the vesting of this power of certification in the hands of any individual who had chanced to receive an appointment as a sanitary inspector. It turns out now, however, that the report stage will not come on till after the holidays—or probably before the end of June. There is still, therefore, time to call attention to the facts of the case. The General Medical Council has done its duty, but a great deal remains to be done. The matter is of interest to every medical officer of health in England and Ireland, and even to the whole profession. The question of what is and what is not detrimental to health is essentially a medical question, and to give to any man who is not required to have the necessary general and special education the statutory right to certify as to both danger and injury to health is to befool the public and to belittle the profession. What is being attempted to-day in Scotland will, if successful, be attempted to-morrow in England. Even now a Public Health Bill for England is being talked of, and as Parliaments are swayed by nothing more than precedents, it behoves the English and Irish medical officers to act without hesitation and delay. Every one of them who has access to a member, either of the Lower or the Upper House, ought to point out the utterly objectionable character of this part of the Bill, and the certainty that its results will be felt more by the public than by the profession. The subject of sanitation is far too important to be left to be dealt with by incompetent hands. Owners of property are learning more and more to realise that it is a moral duty on their part to have their premises in a sanitary condition and to be willing to perform their duty; but in its performance they have at least the right to demand that the complaint in consequence of which alterations in their property are to be undertaken shall be based not on ignorance but on knowledge; and not merely on the knowledge of the "practical man" whose practicality consists in the fact that yesterday he was digging a hole or climbing a ladder, but on the knowledge of the man who has both general education and medical training as a foundation, and who has built on this foundation a special knowledge, both theoretical and practical, of all that relates to the public health. In all seriousness we ask that medical men throughout the country, and medical officers especially, shall take a personal interest in the rectification of this Bill.

THE NEW CHOLERA HOSPITAL FOR CARDIFF AND BARRY.—The official inspection previously to the taking over of the new cholera hospital on Flat Holm Island by the Cardiff corporation was made on May 27th by the health committee. The hospital buildings consist of a ward, pavilion, and a laundry block. The pavilion contains two wards providing accommodation for twelve patients. A crematorium has been erected for disposing of the bodies of any patients who might die from cholera. The buildings, which are well fitted up, are of local stone, the cost being nearly £3000.

Annotations.

"Ne quid nimis."

ISOLATION ACCOMMODATION IN THE METROPOLIS.

DR. ORME DUDFIELD, medical officer of health of Kensington, draws attention in his last monthly report to the disproportionate provision in the hospitals of the Metropolitan Asylums Board for scarlet fever cases as compared with that for diphtheria, some 3800 beds being set apart for the former disease and only 700 for the latter. Dr. Dudfield urges that it would be better, having regard to the much more serious nature of diphtheria and to the liability of those suffering from the disease to complications of an urgent nature, if provision were made to isolate more diphtheria cases, even if such a step necessitated the non-isolation of many scarlet fever cases. There is much to be said for the view taken by Dr. Dudfield, more especially in respect to the chances of recovery of a patient suffering from diphtheria; but from the public health standpoint there is the consideration that scarlet fever is more likely to spread in a household than is diphtheria. Similarly with regard to enteric fever, there is but little doubt that if cases of this disease were nursed by well-trained nurses, who, in their turn, were supervised by thoroughly competent medical attendants, recovery would be rendered more certain than when such cases are treated in the homes of the poor; but, at the same time, from the public health aspect there is less danger to the community from a case of enteric fever than from one of scarlet fever. We are, however, entirely at one with Dr. Dudfield as to the necessity for the more extended isolation of diphtheria. Dr. Dudfield furnishes in the report to which we are alluding an abstract of the number of beds available for the infectious sick of the metropolis, and as the figures may be of interest to those who have not access to the reports of the Metropolitan Asylums Board we reproduce them here. For acute cases of fever and diphtheria there are at present 3459 beds, and for convalescent cases of the same diseases 1707, giving a total provision of 5166 beds, figures which include the "emergency" beds placed in various hospitals during the recent pressure on their accommodation, and which may probably, therefore, be taken as implying a little "overcrowding." In addition to the above provision there are in course of erection the Park Hospital at Hither-green for 548 patients and the Grove Hospital at Tooting for 520 patients, while a site has been procured at Carshalton for 700 convalescent fever and diphtheria patients. The Park Hospital is expected to be ready in July and the Grove Hospital some time next year. In the matter of small-pox provision there are some 1492 beds available, but a considerable number of these are at the present time occupied by scarlet fever patients. In reference to this question of small-pox provision Dr. Dudfield recalls to the minds of the Kensington Vestry the excellent results which accrued from moving small-pox cases from the London hospitals to Darenth—results which have prompted the Local Government Board to insist upon a somewhat similar isolation in the case of all newly erected small-pox hospitals.

THE NEW METROPOLITAN WATER BILL.

"A BILL to Amend the Law respecting the Metropolitan Water Companies" has been printed. As we stated last week, it is but a provisional measure pending the results of the inquiry of the new Royal Commission. By its first clause any water consumer or any local authority may complain to the Railway and Canal Commission that any of the metropolitan water companies has failed to perform

Hosted by Google

some statutory duty. By the second clause any complaint as to the quantity or quality of the water-supply for domestic use will be heard by the same Commission. If in each case provided in these clauses the Commission are satisfied that the companies have failed in their duties, or that a complaint is well founded, the Commission may bring pressure to bear upon the defaulting company to carry out its duties properly or to make the supply efficient both from the points of view of quality and quantity. We regard this measure as of unquestionable public service, and though to an extent it is provisional, chiefly in regard to the authorities to whom appeal has to be made, yet as a legal requirement binding on the companies we have no doubt it will hold good and be approved by the Royal Commission.

PROSECUTION FOR SELLING WEAK LAUDANUM.

A CURIOUS defence was tendered in the Nottingham Summons Court last week by a druggist who was summoned for selling tincture of laudanum which was not of the nature, substance, and quality of the article demanded. It appears that the inspector appointed to purchase samples in accordance with the requirements of the Food and Drugs Act first sent a boy into the shop for a pennyworth of laudanum. When the boy came out the inspector went in himself and asked for four ounces. The defendant served him, but with some hesitation, requesting the inspector to let him filter it, which was not agreed to. The sample, which was divided into three parts in the usual way, was out of the same bottle from which the boy had been supplied. The report of the analyst showed a deficiency of 63 per cent. of alcohol and 90 per cent. of morphia. It would thus appear that the defendant had made the laudanum with water and not spirit. He objected, he said, on moral grounds to sell the poison as it was commonly sold. This plea was obviously useless when the Act requires a drug to conform to a definite standard, or, in other words, to be of the substance, nature, and quality demanded. It would be distinctly serious to supply a medical man with a preparation of laudanum highly deficient in those active principles upon which he so largely depends. The law in regard to the sale of poisons should leave no doubt in the defendant's mind as to his moral position in the matter. Of course, by employing water in place of spirit the active principles of laudanum, chiefly morphia, would not be soluble in the resulting fluid, and the filtered and clear liquid would contain very little of the narcotic. The aqueous mixture would, moreover, in all probability not be uniform, especially on standing, and it is just possible that the last portion left in the bottle would contain a superabundance of the insoluble constituents of laudanum. The line of defence was feeble in the extreme, and the magistrate imposed a fine of £5, thus establishing that an offence, as we certainly think, had been committed.

A PECULIAR FORM OF "TIC CONVULSIF."

DR. FINLEY, of Montreal, has published in the *Montreal Medical Journal* for March, 1897, under this title, a description of a very rare form of family neurosis. The cases both occurred in one family. The mother was said to have had chorea in childhood, and to have been insane before the birth of the elder patient. Her brother also showed some nervous peculiarities. The elder, who was twenty-three years of age when he came under observation, was a French Canadian. His birth was natural, but there seems always to have been some mental dulness, and he did not prove capable of education. Previously to the onset of the convulsive movements he was impelled to carry out any sudden order that might be given—e.g., to drop anything that he might be carrying. On one occasion he rendered a little girl insensible by a blow on the chest at the suggestion of a mischievous individual. His uncle, referred to above, was affected in a precisely similar manner. The symptoms were first noticed in 1890, and in June, 1894, he had a fit, and there were three others in 1896. From the description these appear to have been hysterical in character. The patient also exhibited single twitching movements of the face and various parts of the limbs every few seconds, and in addition there were violent jerking incoördinate clonic movements in attempting any voluntary action, it being quite impossible for him to button his clothes. The movements continued during sleep. Sensation was unaffected, and there was no marked motor weakness. He was very dull and stupid, but not troublesome. A younger brother, twenty years of age, exhibited similar incoördinate movements on voluntary effort, but spontaneous twitching had only been noticed on a few occasions, and then only during sleep. In this case the knee-jerks were somewhat sluggish, but in the elder brother they were active. There were no disturbances of sensation, but in this case there was not so much mental impairment as in the elder one. The younger patient also suffered from fits, apparently epileptic in character, in which he passed urine and had bitten his tongue. The common features of the cases were therefore spontaneous clonic movement which increased during sleep, irregular movements associated with voluntary effort, the occurrence of paroxysms of an epileptic character, and dulness of the mental faculties.

THE POPE ON DIET.

WHEN a man has reached well-nigh ninety years of age—years spent, moreover, in theological and diplomatic fields, speculative and practical—he cannot but have accumulated a fund of personal experience interesting to the rising generation. Of that experience not the least noteworthy must be his mode of life—the rules of conduct he has formally or informally prescribed to himself, and the extent to which these have been observed and modified or finally approved and adhered to. Leo XIII. is such a man, and amid the "cares" of a unique "empire" he has found time to take the younger world into his confidence and, at least on one supremely important side, to record his personal experience for its benefit. That side is "diet," and very significant are the revelations he has to make. All his days a man of fortune—as became his family traditions—he was from the first a votary of "plain living" as the essential condition of "high thinking." His custom was, as laid down in the memorable first chapter of Celsus, "modo ruri esse, modo in urbe, saepiusque in agro" (sometimes to affect a country life, sometimes a city life, with a preference for the fields); "venari, quiescere interdum sed frequentius se exercere" (to indulge in sport, resting between whiles, but oftener taking exercise). He was, it is known, a capital shot, and when (after being Nuncio at Brussels) he held the Archiepiscopal See of Perugia, he would return from the hillside with a good bag of red-legged partridges for distribution to the hospitals—the day's achievement to be celebrated in another pastime, taking the form of Catullian hendecasyllabics or Ovidian elegiacs. As to his eating and drinking, it was simple, sparing, but not ungenerous; he was never, for example (what, indeed, no Italian is), a "total abstainer." His whole rule of life in this respect might be that of one who had read his "Pavy" and his "Roberts," his "Brinton" or his "King-Chambers," with intelligence and profit, but who had formed a system of his own which independently confirmed these authorities. That system he has just given to the world in a series of Latin hexameters, modelled on those masterpieces, the Epistles of Horace, and written in exposition of the text:—"Parco ac tenui victu contentus, ingluviem fuge" (contented with a sparing and

Hosted by Google

simple diet, avoid gluttony). As to the facility and grace with which he reproduces the Horatian manner, this is not the occasion to speak. The matter of his epistolary excursus is more to our purpose. It is an enumeration of the viands and the beverages most suited to lives such as he has led and is leading, and abounds with practical hints well worth the taking. Curiously enough the School of Salerno early in the twelfth century covered similar ground, but its "Regimen Sanitatis" written for Robert the Norman (son of the "Conqueror") is as little to the taste of latter-day hygiene as its Latinity is to latter-day scholarship. Not that the Pope (except for the rhyming distichs) would object to the following:—

"Si tibi deficiant medici, medici tibi fiant
Haec tria: mens laeta, requies, moderata diaeta."
("Where doctors are not, be thy doctors then
Contentment, ease, and moderate regimen.")

Nor can we think that (barring the versification, "Leonine" but not in *his* sense!) he would take much exception to this:—

"Ova recentia, vina rubentia, pinguia jura
Cum similâ purâ naturae sunt valitura."
("Fresh eggs, red wine, and juicy broth to sup,
With wholesome bread, keep nature's system up.")

Decidedly, however, Leo XIII., on every ground, would give "a wide berth" to the distich:—

"Si tibi serotina nocet potatio, vina
Horâ matutinâ robibas et erit medicina."
("The wine that taken overnight has hurt you
May prove, next morning, not without its virtue.")

A comparison, indeed, between the two poems, the Salernitan and this (in the best sense) "Leonine" one, would be an object-lesson in what was considered good diet for a Crusader in the eleventh century and what is found best for a thinker and statesman in the nineteenth. If the test be that of longevity only, the Pope comes off the victor. Tried by other tests, he would also bear the palm—conspicuous example as he is of the compatibility of the highest intellectual activity with the "Parco ac tenui victu" whose virtues he sings at the close of the first part of this poem:—

"De tenui victu haec teneas, his utere tutus,
Ad seram ut vivas sanus vegetusque senectam."
("On simple diet keep this saving line;
A grand and green old age will thus be thine.")

THE SANITARY INSTITUTE AND THE INSPECTION OF MEAT.

THE report of the late Royal Commission on Tuberculosis showed the necessity for the adoption of proper methods to prevent the sale of meat from tuberculous animals, or of meat from healthy animals that has become infected by the slaughterers from diseased carcasses in the processes of dressing. The existing Royal Commission is to report on those methods which are practicable in this country, and is, as we have already said, so much impressed with the general concurrence amongst the witnesses who have been heard as to the necessity of establishing public abattoirs wherever this is possible, both in the interests of the public health and to protect graziers and butchers against the present want of uniformity in the seizure of carcases on account of tuberculosis, that several of its members, with its honorary secretary, Dr. T. M. Legge, have commenced a tour of inspection of foreign cities to study this question. The first cities to be visited are Brussels, Cologne, Berlin, and Leipzig, where the municipal abattoir system has reached a high stage of development. It may be anticipated, then, that the recommendations of the Royal Commission will include the establishment of public abattoirs in all municipal centres, the regular and systematic inspection of all beasts intended for slaughtering, and of all carcasses during processes of dressing, and the adoption of some plan for the gradual abolition of private slaughter-houses. The Council of the Sanitary Institute has for long recognised that a course of instruction in meat inspection formed a most essential part of the technical education of sanitary inspectors, to whom large powers of condemnation are entrusted by the existing Public Health Acts, and to whom will be relegated in many instances those larger duties in connexion with public abattoirs, which are likely to be a feature of the municipal methods of the near future. The Council, therefore, in the spring of 1896 organised in connexion with the sanitary officers lectures and special demonstrations, held at the institute, with regard to the inspection of meat. The students also were taken under competent guidance to one of the London meat markets to see the methods of preparing meat for sale; and demonstrations were given as to the appearances and physical characteristics of healthy meat, and where to look for, and how to recognise, abnormal appearances indicating disease and unsoundness. The demonstrations given in the museum of the institute were rendered possible by the kindness of medical officers of health in various parts of the country in sending up carcasses and portions of animals affected by various diseases. These specimens were carefully explained to the students by the lecturer, and the students were afforded the opportunity of handling and closely examining the various tissues both before and after the demonstration. The following are some of the diseases which have been illustrated: cysticerci; trichinæ; hydatid cysts of lungs and liver; flukes, tuberculosis of lung, pleura, udder, and lymphatic glands; swine fever; septicæmia; milk fever; inflammatory womb of cow; pericarditis; fibroid tumour; joint ill; joint felon; broncho-pneumonia; ankylosis; and slink meat. The numbers of students attending the demonstrations at the meat market in the three sessions were seventy-seven, and at the museum of the Sanitary Institute 233. Many of the specimens have been preserved for permanent exhibition in the museum by immersing them, first, for twenty-four hours in formalin; secondly, for twelve hours in 80 per cent. of alcohol; thirdly, for two hours in 95 per cent. alcohol; and finally, bottling them in a solution of equal parts of water and glycerine. This process has been found advantageous for fixing the colour of the specimens, and for preserving their normal appearances. For the better preservation of the carcasses sent to the museum for demonstration, a large cold storage chamber with well packed double walls, has been specially constructed in the basement. By means of ice specimens may be preserved in this chamber for several days, even in warm weather. Convenient tables for dressing and arranging specimens have also been provided.

WATER CLOSETS WITHOUT WATER.

THE Essex county council having had their attention drawn to the fact that hand-flushed water closets are very extensively used in the county, and that the medical officers of health make constant complaints of nuisances arising therefrom, directed their county medical officer of health to submit a special report upon the subject, and have since caused copies of this report to be sent to all the local authorities in the county. Doubtless it will come as a surprise to many to learn that at the present time water closets without a supply of water laid on are being fixed daily, and that in Essex alone there are thousands of such closets connected with the cottage property in both urban and rural districts. Such, however, is the case, and the county council is doing good work in directing attention to the insanitary nature of such appliances and in endeavouring to get them abolished. Dr. Thresh's report, which is accompanied by illustrations, proves that not only are these closets a nuisance on account of the filthy condition in which they are generally found, but that as constructed the

Hosted by Google

syphon is so easily unsealed that it is almost useless. Whilst urging that their total abolition is to be desired, he points out that the danger of syphonage can be easily overcome if every closet has a ventilating pipe attached to the distal end of the syphon. Unfortunately the traps used have no provision made for any connexion of this kind. The arguments in favour of these closets, economy in first cost, economy in the use of water, and the non-liability to freeze in winter, are discussed, and it is pointed out that the more modern slop closet is nearly as cheap, is much better, probably more economical in the use of water, and is even less likely to be affected by frost. Where water is obtainable, however, a suitable flushing cistern is to be preferred. The procedure necessary to get rid of these abominations is referred to, but the authorities are recommended first to decide that these conveniences are a source of danger to the public health and then to consult with their officers as to the best mode of dealing with them. The serious danger to health resulting from the use of waterless water closets cannot be denied, and it is believed by many of the local health officers that the emanations therefrom have from time to time given rise to outbreaks of diphtheria and typhoid fever. It is to be hoped that the various authorities implicated will seriously consider this report, and act upon the suggestions contained therein.

THE TREATMENT OF TUBERCULOUS ABSCESSES OF JOINTS.

THE treatment of a "cold" abscess is a question about which any two surgeons could probably express at least more than two opinions. As regards that important variety which is connected with tuberculous disease of joints, Dr. Russell A. Hibbs[1] has stated his own view, which is that it should be considerately and watchfully let alone. In support of this proposition he quotes the observations of Cheyne, Warren, and Ogston that such abscesses are generally sterile of pyogenic organisms. He also refers to Volkmann's descriptions of the tuberculous membrane, studded with miliary tubercles, which lines the abscess cavity, and is itself encapsuled in a dense, fibrous case, devoid of tuberculous deposits, and apparently almost impenetrable by the tubercle bacillus. His own observations, extending over four years of hospital and dispensary practice, lead him to think that this form of abscess tends to spontaneous, if slow, absorption or to gradual evacuation by the small aperture contrived by nature, which is in a measure protective against the admission of foreign bacilli. He prefers, therefore, a policy of non-interference, and regards free incision, scraping, and more heroic measures as tending on the whole to complicate the disease by admitting a pyogenetic element, and thus to prejudice recovery by lowering the vitality of the tissues. The science and wisdom of expectancy he understands to consist in supporting by every means the general vital tone, in affording the diseased joint all needful mechanical protection, and in sparing surgical methods except it be now and then to aid an imperfect natural effort at relief by a counter opening or to use an antiseptic douche. Quoting Shaffer,[2] he states that this plan, pursued at the New York Orthopædic Hospital during four years, was successful in obtaining absorption and apparent recovery in 93 per cent. of the cases treated, while the antiseptic operative procedure employed by Lister and Cheyne ("Tuberculosis of Bones and Joints") achieved success in 73·5 per cent. Dr. Hibbs does not attempt any comparison between these two series in respect of the pathological or other condition of the joint after the close of the period of treatment, nor does he furnish any details of the after-history of the naturally absorbed abscesses. His contribution to our knowledge of these cases is, nevertheless, both interesting and suggestive, and the more so when we remember that a combined method exists in the practice of aspiration followed by injection of iodoform in glycerine. It should not be forgotten that this method has been attended by curative results not less effectual, and probably much more speedy, than those attributed to the expectant course which he recommends.

BEATTY *v.* CULLINGWORTH.

THE plaintiff in this case having presented a petition for leave to prosecute an appeal before the House of Lords *in formâ pauperis*, the matter was referred, according to the usual course, to the Appeal Committee, and was duly considered at a sitting of the committee held on May 27th. The petition was dismissed, on the ground, we believe, that there was no *primâ facie* case for further appeal, and that it was unlikely that the House would reverse the decisions of the Court of Queen's Bench and the Court of Appeal. The result of this decision is that if the plaintiff persists in her intention of bringing her case before the House of Lords she will have to conform to the ordinary rules, one of which involves the payment of a substantial deposit as a preliminary proceeding.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ON Thursday, July 1st, two important meetings of the Fellows of the College will be held. At 1.30 P.M. an election of members of the Council will take place. There are five vacancies, Mr. Howes, Mr. Ward Cousins, and Mr. Heath retiring by rotation, and the other two being caused by the deaths of Mr. Oliver Pemberton and Mr. Walter Rivington. Mr. Howes and Mr. Ward Cousins will, we understand, offer themselves for re-election, but Mr. Heath will not. Sir William Dalby, Mr. Rickman J. Godlee, Mr. Edmund Owen, and Mr. Bennett May will also be candidates. The names of candidates with their proposers must be sent to the Secretary not later than Friday, June 11th. At 5 o'clock the half-yearly meeting of the Fellows will be held, and any Fellow who wishes to introduce a resolution must forward it, signed by the mover, to the Secretary not later than Thursday, June 10th.

'CROSS-COUNTER THERAPEUTICS.

OUR Rome Correspondent writes:—To the casualties—already in Italy and elsewhere a formidable list—occasioned by this most dangerous practice Castellammare on the Neapolitan Riviera contributes another of unusually tragic interest. Signor Edoardo Varrelli having consulted Signor Francesco Rega, a leading pharmacist in the town, received from him a pill containing (we are told) "pochi centigrammi" (a few centigrammes) of aconitum napellus. Shortly afterwards it was found that a terrible mistake had been committed and poor Varrelli died with all the symptoms—the burning sensation in the mouth, the "feeling of searedness," the numbness, the cardiac depression, and the dyspnœa—characteristic of aconite poisoning. In what pharmacopœial form the alkaloid was exhibited we are left to conjecture. It may have been (as, indeed, has happened too often before) the potent English aconitine instead of the impure and inert exotic or German alkaloid or mixture of alkaloids passing under that name. All we yet know is that Signor Rega, profoundly impressed by the "accident" and apparently in doubt as to the dose or pharmacopœial form being to blame, experimented on himself with an exact replica of the pill prescribed to his "patient." And he, too, with scarcely less appalling celerity than Signor Varrelli, succumbed, in his own pharmacy, to the preparation. The incident conveys a loud warning to that all too numerous public which, rather than call in a duly qualified practitioner, consults a chemist and druggist, and takes the

Hosted by Google

medicine which it pays for on the strength of the advice which it gets gratis. This "'cross-counter practice" will, I fear, tend to become more common should the Santini Bill (now before Parliament for the exclusion of English-speaking medical men from Italy) pass into law. The tourist or traveller, generally in a hurry, will be at no pains, in the absence of a resident British practitioner, to hunt out an Italian one—with the misgiving, moreover, that neither party to the consultation may have any language in common. He will be apt to think that, "after all" (a fatal phrase, according to Mr. Goschen), the Italian pharmacist is as good as the Italian physician and consult him accordingly. The transaction (to his mind) will have the merit of "despatch"; but whether in the sense recently illustrated at Castellammare it is for himself to consider.

DIPHTHERIA ANTITOXIN AT CHICAGO.

APPENDED to the Bureau and Division Reports for April, 1897, of the Department of Health, City of Chicago, is an interesting statement styled "The Diphtheria Antitoxin Balance Sheet." It contrasts month by month the death rates from diphtheria from 1885 to 1896 inclusive, from which it appears that the average annual rate between 1885 and 1894 was 10 51 per 100,000 living. In 1896 this rate was only 5 9, and in 1895 the figures were somewhat higher. It is calculated that 750 lives had thus been saved in 1896, a saving which "is attributable to no other cause than the use of antitoxin." This statement and the diagram which bears it out are preceded by a report on the total results of the work done by the "antitoxin corps" since its formation as a branch of the Department in October, 1895. Up to the close of 1896 the total number of cases of reported diphtheria visited by the Department physicians was 2981, the total number found to be diphtheria 2436, the total number in which antitoxin was allowed to be used 2302, and the death-rate on these cases only 6·36 per cent., whereas the average mortality previous to the introduction of antitoxin is estimated at 35 per cent. Antitoxin was also employed to "immunise" 2016 persons exposed to infection from diphtheria, and of these 14 were subsequently attacked by the disease. "Experience shows that fully one-half of those exposed under the conditions which obtained in these 2016 cases would have been attacked with diphtheria; and of those attacked 352 or 35 per cent. of the 1008, would have died if not treated with the antitoxin. Only 14 out of the 2016 exposed were attacked, and none died."

PROSPECTIVE GRATUITOUS SUPPLY OF GLYCERINATED LYMPH.

THE answer given by Mr. T. W. Russell in the House of Commons, on behalf of the President of the Local Government Board, on the question of vaccine lymph indicates the probability of a very important change of practice in England. Sir William Priestley had asked a question relating to the future Government lymph service, and he elicited two pieces of information. The first was that changes had already been made permitting public vaccinators to use calf lymph. This we had announced some time since, and, as we explained, the permission means that no public vaccinator resorting to calf lymph will lose his award by reason of his failure to maintain a series of arm-to-arm vaccinations. The second statement related to inquiries that had been made in foreign countries by Dr. Thorne Thorne and Dr. Copeman, and to the probability that, in consequence of these inquiries, glycerinated calf lymph will come to be the future supply of the National Vaccine Establishment, and that this supply is likely to be a gratuitous one. If the supply turn out thus to be gratuitous a considerable change will be effected. Hitherto the proceedings of the Vaccine Establishment have been limited to the gratuitous supply of a small amount of lymph with a view of starting a series of vaccinations which were to be continued by vaccination direct from arm to arm. But a gratuitous supply of glycerinated calf lymph in itself carries with it the abolition—in so far as the Government are concerned—of the use of humanised lymph; and hence the new supply cannot be limited as formerly, but must be so contrived as to meet all demands of registered medical practitioners for all their vaccinations. This will mean a complete change of the existing system; and we can quite understand, as implied in the answer given in the House of Commons, that there may be difficulties in giving effect to the new system until the whole question of our vaccination law has been dealt with by new legislation. The existing law is based on the assumption that it is desirable to vaccinate with fresh humanised lymph from arm to arm; our future law will probably be based on the assumption that it will be best to vaccinate with stored glycerinated calf lymph. The two systems are scarcely reconcilable, and we can well understand that the latter system can hardly be brought into efficient working so long as it is controlled by legislation intended to secure a totally different result. However satisfactory the answer may therefore be, we shall probably have to wait until next session before effect can be given to it.

MULTIPLE TUBERCULOUS ULCERS OF THE STOMACH.

TUBERCULOUS ulcer of the stomach is conceded by all writers on pathology to be of extremely rare occurrence—some, indeed, of the earlier ones considering that organ almost immune from tuberculous infection. Again, some few of the earlier writers claim to have found it with comparative frequency in the necropsies of tuberculous subjects. In the *Johns Hopkins Hospital Bulletin* for April, 1897, is a paper on this subject by Dr. Alice Hamilton, detailing the pathological conditions of three cases in which tuberculous ulcers were found in the stomach. The first case was that of a coloured female aged thirty years. She was the subject of pulmonary and laryngeal tuberculosis. The intestines were the seat of numerous ulcerations. The stomach showed a large number of ulcers, from 115 to 120, scattered over the entire organ, but most thickly in the anterior aspect, near the greater curvature. These ulcers were round or oval, usually smaller than a penny, with rounded, thickened edges, generally smooth and undermined for a variable distance. Microscopically the ulcers varied in appearance, depending upon the extent of their development. In the more advanced stages necrosis of cells existed, with fragments of nuclei. Tubercle bacilli appeared in small numbers along the free surface of the ulcers and singly, embedded in the tissues, among the clusters of epitheloid cells. The second case was that of a male, aged fifty years, who had pulmonary tuberculosis but no intestinal ulceration. The mucous membrane of the stomach was congested, and along the greater curvature, almost over its entire extent, small ulcers occurred, from seventy to seventy-five in number. They presented worm-eaten edges and uneven bases, which sometimes, but rarely, were covered with small granulations. They extended usually only partly through the mucosa. Tubercle bacilli were present in large numbers, and often they occurred in great clumps. The main masses were on the free surface of the ulcers, but they were also found deeper among the glands or within their lumina. The third case (given in an addendum to the paper) was that of a coloured girl, aged eleven years, the subject of pulmonary tuberculosis and general miliary tuberculosis. The serous coat of the stomach was covered with small and large caseous tubercles. Midway between the pylorus and the cardiac orifice on the posterior aspect of

Hosted by Google

the lesser curvature was a large, irregularly oval, crater-like erosion, 3 c.m. by 2 c.m. in size. The edges were raised and undermined. A second smaller erosion was found above this one in the middle of the lesser curvature. In the duodenum, just beyond the pyloric orifice, was a large ulcer with caseous tubercles covering its base. Tubercle bacilli were found in the ulcer in the stomach. In this case the question naturally arose whether or not the ulcerative process in the stomach was merely secondary, having been caused by a lymph gland adherent to the stomach, which was caseous and at first was suspected to have ulcerated through to the free surface. The microscopic examination proved, however, that the process in the stomach was quite independent in its origin, as the still intact muscular wall could be traced along the whole extent of the ulcer between it and the caseous gland behind.

THE CHARITY OF LOAN SOCIETIES.

CHARITY in Ireland sorely needs organisation if we are to believe the report recently issued by a special committee on the management of the hundred or more loan societies operating in that country. The evidence contained in the pages of this document is sufficiently startling even in these days of sensational finance. In it we have to search carefully for signs of an honest policy, to so large an extent has the name of charity—for these loan societies are described as "charitable"—become the cloak of fraud. The all-powerful person in a society of this kind is it appears the clerk. This official, though nominally responsible to the members, is practically free from supervision and as a rule has used his liberty to enrich himself at the expense of his society. Falsification is a frequent feature in his accounts, but whatever in them suffers diminution his own salary does not. It is by the clerk's authority that loans are issued irrespectively of the character or status of the applicant, that assumed and fictitious names are used, borrowers accepted as sureties, fines levied with unwarranted freedom, and, in short, that illegality and informality abound in every department of this most uncharitable system. Thousands of poor peasant debtors suffer in consequence, between 70 and 80 per cent. of the families in one district having been, it is stated, indebted to a society for the past ten years. Charitable grants form a part of the plan of operations under this loan system. For these the surplus accruing to any society is liable, but we are informed that the poor and the sick have gained little from this source of supply. It is long since we have read a more disgraceful history than this record of dishonest and slovenly mismanagement. The special committee appear thus far to have discovered no reason to qualify their own strongly expressed opinions on the conduct of these societies, and it is evident have no intention of shielding them from its consequences.

THE DIAMOND JUBILEE: A SUGGESTION.

WHILE every nerve is being strained to make the Diamond Jubilee procession on June 22nd a success, the fact does not seem to have been realised that on that day perhaps more than on any other occurs a most fitting opportunity for making a lasting patriotic impression upon the public and causing the heart of the people to beat in unison with that of their Sovereign. On that day Her Majesty the Queen will be the one object upon which every thought will be centred, and upon her will rest, not only the eyes of the people of the vast British Empire, but also the eyes of the peoples of the world. On that day our people will realise that Her Majesty, surrounded as she will be by representatives of the British Empire throughout the world, is the emblem—and the fitting emblem—of the greatness, the power, and the glory of a nation who, holding out her arms from England, her home, to the uttermost ends of the earth, has gathered to her bosom the heathen and the slave and has scattered broadcast over their lands the blessings of civilisation. For the Diamond Jubilee to be the success which we all wish it to be there must be complete sympathy between the people and the Queen and Empress, who represents in her person the empire upon which the sun never sets. This being so, we can conceive of nothing which would better tend to bring about such a desirable consummation than the official issue of a souvenir taking the form of a programme of the procession, illustrated by thumb-nail sketches in colours (if possible) of the types of those taking part in it, in the exact order in which it will pass the public. The man in the crowd would then be able to take an intelligent interest in all that passes his eye, and he whose interest has been aroused by the expectation of brilliancy and pomp only would awaken to the fact that he, too, is a member of the British Empire, and would then realise that in his loyalty to its figure-head depends its stability. Such a souvenir should not cost more than one penny, but the psychological result would be to the nation and to the Government such that the country would be the gainer even if the souvenir were given away gratis. We are well aware that the time now left for such an undertaking—one of very considerable magnitude—is short; but it is wonderful what the British race, when once they have made up their minds to a definite course of action, can do, and we appeal to the authorities to consider favourably our suggestion.

THE OMNIBUS IN SUMMER.

"FULL outside" is the usual announcement of the omnibus conductor to the would-be passenger when the fine, warm weather of the summer months has set in. And there are few that can endure sitting inside on account of the oppressive heat, the character of which can only be likened to a glass house under full bombardment of the sun's ray. Those, of course, who are anxious to arrive at their destination at a certain time—as, for instance, to catch a train—are compelled to go inside and endure the oppressive and stifling heat as best they can. Surely this discomfort need not be. Why cannot the fixed glass windows be made to slide up and down as in a railway carriage, or, as we believe, in many of the tramcars? We are quite certain that there would be very few persons on a hot sunny summer day who would object to every window being down. It would certainly pay the companies to afford this advantage, since whereas on many days in the summer they now carry only fourteen passengers outside they would secure twelve additional passengers inside if the conditions could be made as agreeable there as on the top in the breeze. As it is, the omnibuses are commonly empty within but full outside, which, apart from any other consideration, adds top-heaviness to the vehicle, and may be dangerous and conducive to capsizing of the vehicles. If the omnibus companies would adopt the simple expedient we suggest it would be a source of increased income to them and a decided boon to the public.

AVULSION OF THE RECENTLY INVERTED UTERUS.

WE record this week an extremely interesting case reported by Mr. Hickson Smith. A patient had been attended in her labour by a midwife. The child was born while she was on her hands and knees. After separating the child and putting the patient to bed the midwife observed that there was a large lump protruding from the vagina. This she thought was the head of a second child, and she pulled on it for three-quarters of an hour till it came away. Mr. Hickson Smith, who saw the patient two hours after delivery, found her

Hosted by Google

suffering from shock, and on making an examination found that the examining finger passed freely about among the intestines. No uterus or cervix could be felt. When he examined the lump which the midwife had pulled away he discovered that it was the whole uterus and cervix, with the peritoneal coat, and there was one Fallopian tube attached to it without the corresponding ovary. The patient made an uninterrupted recovery. Inversion of the uterus is fortunately an extremely rare accident. When it occurs the nature of the case is generally evident. But there are many cases scattered through obstetrical history in which the inverted uterus has been mistaken either for the head of a second child, as in Mr. Hickson Smith's case, or for a second placenta. In some examples of the former mistake the forceps even has been applied. Cases like the one recorded by Mr. Hickson Smith are referred to by Dr. Barnes as follows: "More marvellous still, cases have occurred in which the recently inverted uterus has been torn away by the attendant, the patient recovering." The same occurrence is also mentioned by Churchill in his "Diseases of Females" in relation to the question of the extirpation of the whole uterus for cancer: "In one instance the inverted uterus was removed by a midwife (Bernhard); in others it has been torn away (Fignet-Siebold). There are cases on record where the issue was less fortunate." The last sentence evidently implies that in the instances given the patients recovered.

MEDICAL OFFICERS OF HEALTH AND THE DIAMOND JUBILEE.

IT is satisfactory to note that certain medical officers of health are taking advantage of the spirit of loyalty which is finding such remarkable expression all over this great empire of tracing back in their current annual reports the vital statistics of their districts during the years covered by Her Majesty's reign. This action on the part of medical officers of health seems to us to be an especially happy and graceful one, and one which is, furthermore, calculated to interest the members of district councils and other local bodies. The spirit of retrospection is "in the air," and district councillors will read during 1897 summaries of progress which they would be loth to peruse on any other occasion. The progress of sanitary science during the past sixty years will rank high among the events of the nineteenth century, and it is gratifying to learn that in some districts the Diamond Jubilee is to be celebrated by some measure of sanitary reform which is bound to prove a substantial and lasting blessing to the inhabitants of the district. Prominent among such measures as this is to be recorded the cleansing of the "Notting-dale special area," which is situated in the wealthiest parish in the world—the parish of Kensington. This "special area" Dr. Orme Dudfield, the medical officer of health of the district, has shown to possess an altogether abnormally high death-rate, and although the measures which it is proposed to take to commemorate the Jubilee may not for some time find an expression in a diminished death-rate, they cannot fail to infuse more brightness and cleanliness into the lives of the luckless people who inhabit the area in question. It is, however, to be regretted that the committee appointed to carry out the improvements have not seen their way to adopt Dr. Dudfield's suggestion for the amelioration of the condition of the inhabitants by the provision of a certain number of healthy and decent homes.

SALFORD WORKHOUSE.

FROM time to time cases occur which show that even in workhouses, which in general are well managed, perfection has by no means been attained. One night the week before last a constable was hailed by a cab-driver and told that a woman in the cab had been refused admission to the workhouse. He got on the cab and told the man to drive to the Cross-lane police station, Salford. Before getting there the woman gave birth to a child in the cab. Mr. Wolstenholme was called and said she must be taken back to the workhouse. On arrival there great difficulty and delay were experienced in gaining admission. The constable had to climb the gates and, according to the report, to ring a bell for twenty minutes before anyone appeared. It seems there is a night bell at the entrance, but it is so well hidden behind a pillar that the constable, with four years' knowledge of Salford, had never discovered it. This "unfortunate incident" was referred to the House Committee for inquiry, the result being that on Friday last it was recommended "that a bell be placed on the outside of the workhouse." This was most thoughtful, as it would be so much more useful than if placed in the inside. Mr. Somers, one of the guardians, said there was not an institution in Manchester or Salford where so many inmates—about 1000—were housed together without a night porter being on duty. He would have a night porter, but not a bell outside, as "mischievous people would delight in ringing it." Another guardian said it was "quite right that in case of fire in the house they should have a man so placed as to be able to give information outside." There will be general agreement with this proposition, but it may be hoped there is already some provision inside for dealing with fire. The possible repetition of the "unfortunate incident," or of some urgent call for admission at night, does not seem to be contemplated, for—so far as can be gathered from the report—there is to be no bell, but the question of the appointment of a night watchman is to be referred to the House Committee.

DR. W. HALE WHITE will deliver the Croonian Lectures, on "The Means by which the Temperature of the Body is Maintained in Health and Disease," at the Examination Hall, Savoy, W.C., on the following Tuesdays and Thursdays at 5 o'clock—June 15th, 17th, 24th, and 29th.

H.R.H. THE DUKE OF CAMBRIDGE, K.G., will preside at the dinner commemorative of the twenty-first anniversary of the Sanitary Institute on Wednesday, July 7th, at the Holborn Restaurant."

THE annual dinner of the West London Medico-Chirurgical Society will take place at the Trocadéro Restaurant, on Friday, June 11th. Lord Lister is expected to be present.

THERE will be a meeting of the Hospital Reform Association at Bristol on June 18th, at 4 P.M.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Knoblanck, First Assistant in Professor Oelshausen's gynæcological clinic, has qualified as *privat-docent*. Dr. Heinrich Albert, the well-known hygienist has been granted the title of Professor.—*Bonn:* The title of Professor has been conferred upon Dr. M. Wolters, *privat-docent* of Dermatology.—*Breslau:* Dr. E. Kaufmann, *privat-docent* of Pathological Anatomy, has been appointed Extraordinary Professor.—*Gröningen:* Dr. Albert Döderlein, Extraordinary Professor in Leipzig, has been appointed Professor of Midwifery and Gynæcology in succession to Dr. Sänger who has retired.—*Kieff:* Dr. Alexander D. Pavlovsk, Extraordinary Professor of Surgical Pathology, has been appointed Professor.—*Marburg:* Dr. Jacob Zumstein, *privat-docent* of Anatomy and Prosector, has been granted the title of Professor.—*Prague (Bohemian University):* Dr. Ottokar Kukula has qualified as *privat-docent* of Surgery.—*St. Petersburg (Military Medical Academy);* Dr. N. A. Veliarminoff, Extrordinary Professor of Surgical Pathology has been appointed Ordinary Professor.

SICILY

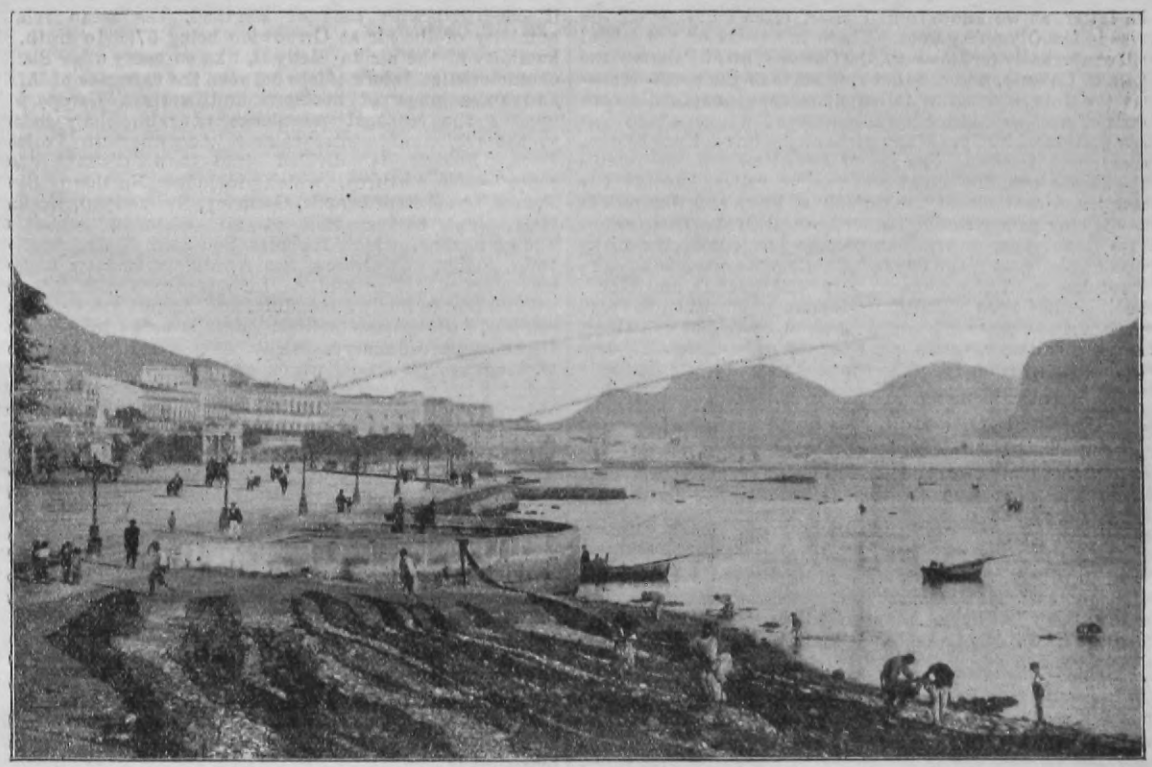
AS A HEALTH RESORT.

I.

Geographical Position of Sicily; the Central Island of the Mediterranean. — Chequered History of Sicily. — Great Importance of Sicily as Contrasted with Sardinia, Corsica, Crete, or Malta.—Modes of Approach to Sicily.—First Impressions of Palermo.—Richness of the Sicilian Flora.—Varieties of Racial Type.—Poverty and Begging.—Institutions of Palermo.—Geological History of Sicily.—General Character of the Scenery.—Coast and Interior.—Diboscamento.—General Sketch of the Climate of Sicily.

THE geographical position of Sicily is the key to the climatic and ethnic characteristics of the island, and affords a clue to the singularly interesting and chequered course of Sicilian history. Sicily is the central island of the Mediterranean. It lies almost midway in the great central sea between Spain and Asia Minor. It is nearer Tunisia—from which it is divided by a channel about eighty miles wide of, for the most part, quite shallow water—than it is to Campania or to Sardinia. Politically a part of Europe, Sicily is in reality an intermediate territory between east and west, between north and south. Hence it has been the meeting place of different nations, the battle-ground of contending dynasties and of rival creeds. It was on the coasts of Sicily that the first Greek colonies settled in that great swarming period of the Hellenic race in the eighth century before Christ. To the same coast came the Phœnician trader from Tyre and his kindred from Carthage. It was in Sicilian waters that Rome and Carthage fought out the first round in their great duel for the supremacy of the world, and at later epochs of the world's history Sicily has been the scene of the strife of Saracen and Norman, of Frenchman and Swabian, of Spaniard and Piedmontese. Several times in the course of her eventful history has Sicily been the seat of a strong local Government—under Dionysius in the days of Syracusan supremacy, under the Norman kings, and under Frederick II, who so nearly inaugurated the Renaissance amidst the orange-groves of Palermo, but her more usual fate has been that of the victim and plaything of more potent or more warlike neighbours. As Manfred in Schiller's *Braut von Messina* says:—"Das Land kann seine Kinder nicht schützen" (The country is unable to protect its own children). Phœnician and Greek, Roman and Carthaginian, Vandal, Goth, and Byzantine, Norman and Saracen, Frenchman, Swabian, Spaniard and Italian, have fought for the possession of Sicily, and have alternately covered the land with waving harvests and artistic beauty or filled it with confusion, rapine, and bloodshed. The course of history marks out Sicily as differing essentially from the rest of Europe, and as possessing peculiar relations with the African continent and with the Orient. It will be seen hereafter that these facts have an important relation to the meteorology and climatology of the island.

The position of Sicily in history is in striking contrast with that of the other great Mediterranean islands—Sardinia, Corsica, Crete, and Malta. Sardinia gave a name to a ruling dynasty, but its own internal history is obscure and unimportant. Corsica is chiefly remembered as the birthplace of Napoleon. The importance of Crete is confined to mythical times, to the days of Minos and Dædalus. Malta is simply an outpost of British commerce and British arms, But Sicily has never ceased to be the scene of great events, and at one time or another has played a leading part in the fortunes of all the great nations which have ruled along the shores of the Mediterranean. Hence the singular charm of Sicilian history; hence the richness of the land in artistic remains, in literary associations, in ecclesiastical architecture. Wherever we go in Sicily we are upon enchanted ground. Homer, Pindar, Thucydides, Theocritus, Virgil, Cicero—to mention a few great names out of many—abound in allusions to Sicily. The rocky height of Enna reminds us of Demeter and Proserpine. The Etna country is strewn with myths of Ulysses and Polyphemus, Acis and Galatea, Titans and Cyclopes, Enceladus and Vulcan. The ruin and desolation of Segesta and Selinunte, of Girgenti and Syracuse tell their moving tale of the fleeting nature of human things, and are eloquent of extinct ambitions and outworn creeds. Wherever we go in Sicily we are oppressed by the weight of the mighty past, and we come to realise the almost literal truth of Professor Strafforello's picturesque statement "Ogni zolla in questa paese è storia" (Every clod in this land is history).



Sicily may be approached (1) by rail from Naples to Reggio, whence the traveller is ferried to Messina, the entire journey from Naples to Messina occupying about 14 hours; or (2) by steamer from Naples to Palermo, a passage of from 11 to 12 hours; or (3) by steamer from Malta, a passage of from 7 to 8 hours. By either the first or the second route the journey from London may be put down at three days, by the third route at about eight days. If the traveller selects the second route, which offers many advantages, he sails from Naples at 8 P.M. in one of the fast and comfortable steamers of the Florio-Rubattino Company, and at dawn the following morning he finds himself in sight of the picturesque northern coast of Sicily. The approach to Palermo is justly celebrated. The beautiful bay flanked by Monte Pellegrino and Monte Catalfano, the rich expanse of the Conca d'Oro with its innumerable orangeries and lemon groves and its girdle of enclosing mountains, in the near distance the busy port, handsome esplanades, and luxuriant gardens of the Sicilian capital, and on the horizon the snowy summits of the Madonian mountains—these constitute a scene which rivals Sydney Cove, the Bay of Naples, or the Harbour of Rio Janeiro. Monte Pellegrino, a solid mass of naked limestone, would seem to have exercised a singular fascination over Goethe. In one passage of his "Italienische Reise" he calls it "the most beautiful promontory in the world," and in another passage of the same work he says: "Seine schöne Form lässt sich mit Worten nicht beschreiben" (Its beautiful form cannot be described in words). It is, indeed, an imposing mass, but it owes no small part of its charm to the ever varying play of colour which Sicilian sunshine and Sicilian air produce on its bare sides and denuded summit. If the weather be favourable the first impressions of the traveller on landing in Palermo will be in a high degree vivid and pleasing. The brightness of the sunshine, the softness of the air, the richness of the flora, the variety of the architecture—Norman, Gothic, Moorish—the diversity of ethnic type, the gay dresses and *al fresco* life of the people, the streets planted with the slender plane or the graceful pepper tree, the gardens waving with palm trees and ablaze with Judas tree and *Erythrina*, the picturesque Sicilian carts, the noisy but musical cries of the multitude of hawkers, the jingle of mules' and donkeys' harness, the clang of the goat bells,—these make a varied and charming scene only to be enjoyed in Sicily on a fine morning in spring or early summer. A closer inspection of Palermo will, on the whole, justify the first favourable impressions of the traveller. An air of vigorous life and progress pervades the Sicilian capital. The port is crowded with steamers from all parts of the Mediterranean; new streets, wide and well planted, are springing up; and in the suburbs handsome villas and beautiful gardens abound. The botanist will find in the singularly rich and varied flora an inexhaustible field of observation. To this subject further reference will be made, as it has important bearings upon climate and health. The student of ancient art and mediæval architecture will find ample scope for his researches in the admirable museum, the beautiful Cappella Palatina, the cathedral, so impressive without, so disappointing within, the numerous churches of different epochs, and, above all, in the grand cathedral of Monreale, which is no unworthy rival of St. Mark's, Venice. The historical inquirer can here work an inexhaustible mine. Carthage, Greece, and Rome have all ruled here. Vandal, Goth, Saracen, Norman, Spaniard, Frenchman, and Italian have fought for this land and have made history in this corner of Sicily. A chequered history has left as its legacy a remarkable diversity of racial type. Here we see a pure Greek face, like a Caryatid from the Erechtheum; there such a face as Titian loved to paint—oval, with dark, lustrous eyes, low forehead, full cheeks, and small nose and mouth; now we are reminded of the Spanish occupation by an unusual hauteur and dignity of pose, and again in the full lips and swarthy hue of some of the lower classes we apprehend the possibility of negroid admixture. The prevailing type is, however, unquestionably Italian and

Hosted by Google

not to be readily distinguished from that of Campania or Calabria. The agreeable impression which Palermo makes upon the traveller is not, however, unmixed. The cleanliness of the city, though superior to that of many Italian towns—e.g., Naples or Venice—still leaves much to be desired. Poverty is much in evidence, and strikes the observer the more inasmuch as it exists side by side with wealth and luxury, and begging—"l'eccessivo e nauseante accattonaggio che si esercita per le strade di Palermo" (the excessive and repulsive mendicancy which is practised in the streets of Palermo) is the frank but unexaggerated language of the "Associazione pel Bene Economico" on this subject—is practised to a truly distressing extent. But we must remember that we are in Southern Europe and that such things are, unhappily, the norm of the latitude.

Palermo is not merely the capital of Sicily, it is the true metropolis of the island, the centre of all that is most vigorous in its commercial, intellectual, and social life. There is a university attended by 1100 students, there are numerous schools and philanthropic institutions, a well-equipped astronomical and meteorological observatory, several admirable botanical collections, many hospitals, libraries, and scientific collections of various kinds. In one of the hospitals there exists an operating theatre thoroughly equipped with every modern appliance and in all respects comparable to the theatres of the leading hospitals in London, Paris, and Berlin. In the same institution a new detached ward for operation cases bore over its portal the honourable title, "Sala di Lister." Perhaps the most interesting of the hospitals of Palermo is the "Ospizio Marino," erected in an open and healthy locality near the sea for the treatment of cases of "scrofula" and rickets, especially for those requiring operation. The institution is a model of cleanliness and efficiency, and it is not surprising to learn that the results of treatment obtained there have been most gratifying. There are many evidences of public spirit and philanthropy in Palermo, and it is but just to add that in all such works the members of the English colony have been pre-eminent. The subject of the suitability of Palermo as a health-resort may be reserved for future consideration. This question will more profitably engage attention after we have dealt fully with the meteorology and climatology of Sicily as a whole. The present article is preliminary, and is confined for the most part to a general sketch and to first impressions.

Sicily has an area of 9935 square miles, less than one-third that of Ireland. It is of comparatively recent geological formation. Geology shows that the fauna and flora of Sicily are more ancient than the island itself. The greater part of the island was converted from the sea after the Mediterranean was already populated by nearly all the actually existing species. The separation from Italy took place long before the advent of man. The mountain range which runs out towards the north east of Sicily is composed of crystalline rocks similar to those forming the parallel range of Aspromonte in Calabria, but upon these rest sedimentary strata belonging chiefly to an early tertiary epoch. A subsequent land connexion took place by the elevation of the sea bed, and it is probable that there was a direct post-tertiary connexion also with the African continent. The fossil fauna (e.g., the great quantity of remains of pachyderms) and the great subterranean plains bear testimony to the ancient connexion between Sicily and Africa. From Marsala to Cape Bon in Tunis there still extends to-day a subterranean bridge 120 kilometres long, the depth of the sea being only a little more than 200 metres. "La Sicilia è dunque," says Professor Strafforello, "per così dire, una gran pila rimasta in piedi di questo gran ponte terrestre sommerso da lungo, ma che va del continuo lentamente risollevandosi." (Sicily is then, so to say, a great pillar still remaining above ground of this great terrestrial bridge, submerged long ago, but continuously rising slowly.) The superficial strata of Sicily are mainly tertiary, and the great height attained in some places by tertiary rocks (e.g., Castrogiovanni, the ancient Enna, 3270 ft. above the level of the sea) is one of the chief geological peculiarities of the island. The Monte Peloritani in the north-east are crystalline rocks belonging to the primitive formation, and the mountains of the north coast, with their ramifications to Monte Giuliano (the ancient Mount Eryx), and Monte San Calogero, near Sciacca, are composed of secondary calcareous rocks. The plains of Catania, Terranova, and Licata are quaternary and alluvial. Mont Etna, which stands apart from the other mountain systems of Sicily and rises to the

Palermo.

Hosted by Google

height of 10,835 ft., is the youngest mountain in Sicily and belongs to geological times comparatively recent. Sicily is a very mountainous country and has hardly any considerable plains, the Piana di Catania and the Campi Geloi being the chief. The north coast is almost uniformly rocky and precipitous and abounds in striking and picturesque scenery. From Lilybœum (Marsala) to Gela the coast is composed of clay and is almost harbourless. From Gela to Cape Pachynus (Cape Passaro) the coast is low but rocky. From the latter point until the volcanic region of Etna is reached the coast is varied with deep bays and rocky promontories. Several good harbours are found on this part of the coast, notably the Porto Grande of Syracuse and the Bay of Augusta. From the mouth of the Simeto to that of the Alcantara—i.e., the region between Catania and Taormina—the coast is composed of lava and other volcanic material. The scenery here attains a high degree of beauty and grandeur. The centre of Sicily belongs entirely to the tertiary formations—calcareous or arenaceous—and consists of rocky uplands intersected by deep valleys. The fertility of Sicily is lauded by the ancient writers, and we know that the island was one of the great granaries of the Roman Empire. At an earlier period Sicily was famous for its oxen and its horses—the latter, as we know from Pindar, often carrying off the prize in the Olympic games. There are parts of the island still exuberantly fertile—e.g., the Conca d'Oro of Palermo, the Plain of Catania, and the rich vine lands of the north-west—but the fate which has fallen upon the once fertile corn lands of northern Africa has also descended upon a considerable portion of Sicily. Many parts of the interior are barren, naked, and treeless. Ranges of bare limestone mountains fatigue the eye, and silent and sombre valleys bewilder the traveller, who thinks of the worship of Flora and who recalls the glowing panegyrics of Theocritus and Ovid. There seems little doubt that a grievous change has come over many parts of Sicily since the days of the Roman supremacy. The island has been the scene of perpetual warfare and bloodshed. It has been pillaged by Roman pro-consuls, ravaged by Saracen conquerors, and exhausted by feudal exactions. One of the greatest evils has been the deforesting—*diboscamento*—of the country. The once luxuriant forests of Sicily have almost disappeared, with the exception of some isolated regions, such as the confines of Mount Etna and the Madonian Mountains, where the *ilex* and *castagna* still flourish. This *diboscamento*, which has taken place since the sixteenth century and has gone on rapidly in recent times, has been due to various causes—the poverty of the country, the dread which the peasantry have of the injury believed to be inflicted on the crops by the small forest birds, &c. The effect of the deforesting has been to diminish the rainfall of Sicily, to increase the tendency to drought in many parts, and to impair the once extraordinary fertility of the island. On the other hand, the cultivation of Sicily has recently made considerable progress. The cultivation of cereals and of some trees, especially the "agrumi"—a collective term which includes oranges, lemons, and citrons—has had a considerable development. The Saracens inflicted many woes upon Sicily, and the story of their occupation is written in blood and fire; but if the tradition be true which attributes to them the first introduction of oranges and lemons to the country, they have been amongst its greatest benefactors.

The climate of Sicily belongs to the warm marine class. It is characterised by great equability and freedom from extremes, either annual or diurnal, a high proportion of warm, bright, sunny days, moderate humidity, a moderate rainfall, a considerable amount of wind, and comparative exemption from fog, mist, or severe cold. Warmth, mildness, brightness, and equability are the predominant notes of the Sicilian climate. With the exception of an occasional day of sirocco, when the thermometer may rise to 100° F. in the shade or upwards, extreme heat is very rare, and in the lowlands and upon the coast-line extreme cold is unknown. Snow rarely falls at the sea level, and the thermometer only very exceptionally—perhaps four of five times in the year—touches freezing-point. The lowest recorded temperature at Palermo or Catania rarely in any year falls below 28° or 30° F., and in many winters never reaches freezing-point. The mean temperature of the warmest month, July, at Palermo is 26·03° C. (= 78·85° F.), and at Catania 26·65° C. (=79·9° F.), while the mean temperature of the coldest month, January, at Palermo is 10·89° C. (= 51·6° F.), and at Catania 9·73° C. (= 49·5° F.). The mean daily range of temperature is 6·7 C. (= 12° F.) at Palermo, and 7·7° C. (= 13·8° F.) at Catania. These figures indicate a very high grade of equability, annual and diurnal. The mean annual temperature is 18·15° C. (= 64·67° F.) at Palermo, and 18° C. (= 64·4° F. at Catania. Palermo has an average of 167 "giorni sereni"—i.e., days of cloudless sunshine—in the year, and in addition it has an average of 62 "giorni misti"—i.e., "mixed" days, or days of partial cloud and partial sunshine. Catania has an annual average of 164 "serene" days and 118 "mixed" days. As the days denominated "misti" by the Sicilian meteorologists would be called fine, if tried by the English standard, we may say that Palermo has, on an average, 229 fine days in the year, and Catania on an average no less than 282 fine days. We need not stay to comment upon the high importance of these figures to the invalid and health-seeker. Palermo has a mean annual rainfall of 758·68 mm., = 29·87 in., which falls upon 116 days. Catania has a mean of 542·7 mm., = 21·37 in., which falls upon 86 days. The mean relative humidity of the air is 65·4 at Palermo, and 61 at Catania. These figures show that while the climate of Sicily may be described as "damp" if compared with that of Cairo, where the mean relative humidity is only 58·4, it may be described as "dry" if compared with that of England, the mean relative humidity of the air at Greenwich being 87. In truth, the humidity of the air in Sicily is, like so many other Sicilian characteristics, intermediate between the extremes of Africa and some parts of northern and western Europe. As regards the seasonal prevalence of rain, Sicily belongs to the region of winter rains. According to Professor Dove, Europe is divided into two distinct "rain zones"—the northern, which includes Northern Spain, France, the British Islands, Germany, Switzerland, Northern Italy, &c., having rain at all seasons; while the Southern zone, which includes Southern Spain, Southern Italy, Sicily, and Greece, has a rainless summer and the maximum rainfall in winter. In accordance with this law, we find that in Sicily June, July, and August are practically rainless, and that the heaviest rainfalls occur in November, December, and January. Sicily has a considerable amount of wind, though strong winds and storms are not frequent. Palermo has an average of only thirty-three days designated as "ventosi" (windy) in the year. The sirocco is one of the most serious drawbacks to the Sicilian climate. It is most frequent at the equinoctial seasons and is rare in winter. All these questions will be more fully dealt with in a subsequent article. For the present it is sufficient to say that Sicily has the mildest and most equable climate in Europe, that extremes of heat and cold are rare, that the proportion of bright sunny days is remarkably high, that the humidity of the air and the rainfall are moderate, and that the climatic conditions generally are favourable both for the healthy individual and for many cases of debility and disease.

The above is a short sketch of the general features of the climate of Sicily. In the next article the subject will be considered more in detail, and full statistical information will be given.

[Our Special Commissioner, who has been able to collect full details regarding the meteorology of the most important localities in the island, desires to acknowledge his indebtedness to the following gentlemen for much information and kind assistance in connexion with this department of his inquiries: Professor De Lisa and Professor Zona, of the Royal Observatory of Palermo; Signor Antonina Mascari, of the Royal Observatory of Catania; the Marchese di Gallidoro, F.R.M.S.; Signor Guiliany, Director of the Royal Meteorological Observatory of Syracuse; Professor Ciofalo, of Termini; Professor Lancetta, Director of the Observatory of Girgenti; Professor Ughetti, of Catania; and Dr. Palumbo, of Castelbuono.]

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

Report of the Medical Superintendents upon the Use of Antitoxic Serum in the Treatment of Diphtheria in the Hospitals of the Metropolitan Asylums Board during the Year 1896.

THIS report, which has just been issued, constitutes the most exhaustive and elaborate statistical study of the antitoxin treatment of diphtheria which has yet appeared. The

Hosted by Google

treatment has been continued during the past year in a most systematic manner in all the hospitals of the Board, with the exception of the North-Western Hospital, and the report is based upon the facts observed by the medical staffs of the hospitals, collated and analysed in a most careful manner. Excluding the North-Western Hospital, it appears that this treatment was pursued in 71·3 per cent. of the total number of cases admitted, its employment not being had recourse to in moribund or hopeless cases, or in those which were doubtful in nature or so mild as not to require any specific treatment. Altogether, there were 2764 cases thus treated, of which 717 died—a mortality of 25 9 per cent., ranging from 32·3 per cent. at ages under five years to 4·2 per cent. at ages of twenty years and upwards. The notable fact that the best results are obtained by the early adoption of the treatment is clearly brought out, for of all cases at all ages in which the treatment was commenced on the first day of the patient's illness the mortality was only 5·2 per cent., for those in which treatment began on the second day it was 15·0 per cent., on the third day 21·9 per cent., on the fourth day 27·8 per cent., and on the fifth day and upwards 31·7 per cent. The value of these results is strengthened by the fact that the proportion of the very young was much greater amongst those treated by antitoxin than amongst those not so treated; thus in the antitoxin series 48·6 per cent. were under 5 years of age, and 13 per cent. above 10 years, whilst in the non-antitoxin series there were 31·1 per cent. under 5 years and 36·7 per cent. above 10 years. Another example of the greater comparative severity of the antitoxin series is to be found in the fact that in this group the percentage of laryngeal cases was 17·6 as compared with 1·9 in the non-antitoxin series. In order, however, to arrive at a definite conclusion as to the effect produced by antitoxin, a comparison is made between the age-incidence and mortality of all cases of diphtheria (whether treated by antitoxin or not) treated in the year 1896 with those treated in the hospitals of the Board in 1894, when antitoxin was not employed. In 1896 the total number of cases admitted was 4175; 871 deaths, or 20·8 per cent. mortality. In 1894 there were 3042 admitted; 902 deaths, or 30·8 per cent. mortality. The comparison is even more striking when the figures are grouped according to the day of disease at which the cases came under treatment; for, as will be seen from the accompanying Tables II. and III. (in the Report the figures for each year of age up to five are separately given), the difference in mortality between the 1894 and 1896 cases admitted on the first day is 22·5 per cent. and 4·7 per cent., on the second day 27·0 and 12·8, on the third day 29·4 and 17·7, on the fourth day 31·6 and 22·5, on the fifth day and after 30·8 and 24·6.

TABLE II. (*condensed*).—*All Cases of Diphtheria, 1896.*

Day of disease.* / Ages.	1st. Cases.	1st. Deaths.	2nd. Cases.	2nd. Deaths.	3rd. Cases.	3rd. Deaths.	4th. Cases.	4th. Deaths.	5th and after. Cases.	5th and after. Deaths.	Total. Cases.	Total. Deaths.	Mortality per cent.

Mortality per cent.	—	22·5	—	27·0	—	29·4	—	31·6	—	30·8	—	29 6	—

* Day of disease = day of disease on which the patient was admitted to hospital.

Under ten years.	First day.	Second day.	Third day.	Fourth day.	Fifth and later.	Total.
1894.						
Cases	111	395	458	420	862	2246
Deaths	28	141	182	168	317	836
Mortality	25·2	35·7	39·7	40·0	36·7	37·2
1896.						
Cases	71	469	638	636	1480	3294
Deaths	4	71	140	171	428	814
Mortality	5·6	15·1	21·9	26·8	28·8	24·7

It is remarked that the clinical, rather than the bacteriological, evidence was taken as the criterion of diagnosis, and it is interesting to learn that in only 4 5 per cent. did bacteriology fail to confirm this diagnosis, the mortality rate amongst those cases being 27·7, or higher than the general mortality for the year. Thus, then, the difference in mortality between the years 1894 and 1896 was, on the whole, 8·8 per cent., amounting to 365 lives saved by the adoption of the treatment in the latter year. As shown by the following figures, the contrast is the more striking when the mortalities at different ages are compared. For—

	Under 5. Per cent.	Under 10. Per cent.	Under 15. Per cent.
1896.—Antitoxin cases, mortality...	32·2	27·9	26 6
1896.—All cases ,,	30·2	24·6	22·6
1894.—All cases ,,	47·4	37·2	33 6

And this in spite of the fact that the average number of cases under five years was higher in 1896 than in 1894.

One of the most striking effects of the use of antitoxin which has been testified to by every physician who has had experience of it is in the diminution of severity that it induces in cases where the larynx is implicated. This is amply borne out by these returns, for whereas in 1894 the mortality amongst these laryngeal cases was 62·0 per cent. in 1896 it was 29·6, or excluding the Fountain Hospital, which does not enter into the 1894 return, 30·9 per cent. Again the mortality after tracheotomy which was 70·4 per cent. in 1894, was 41·0 (or 42·5) per cent. in 1896, although in the latter year the proportion of laryngeal cases submitted to this operation was 56 as compared with 41 per cent. in 1894.

The same comparative statistics are given in respect to the frequency of complications of the disease as follows:—

	1894.	1896.
Albuminuria	24·1	53 4
Nephritis	1·2	0·5
Paralysis	13·2	21·3
Pneumonia, lobar	0·3	0 5
,, lobular	1·6	2·5
Relapse of disease	0·9	1·6

It must be remarked that the increased attention paid to

Hosted by Google

the detection of albuminuria goes some way to account for the larger figures of 1896, whilst the greater proportion of paralysis, and, perhaps, also of lobular pneumonia is confirmatory evidence of the larger proportion of survival from the initial dangers of the diphtheria virus.

As regards effects probably incidental to the injection of antitoxic serum itself it may be noted that a rash was observed in 35·2 per cent. of the cases treated, joint pains occurred in 6 5 per cent., pyrexia following injection in 19·8 per cent., whilst in only 1·2 per cent. did an abscess form at the site of the injection. As compared with 1895 the practice has been improved by the use of serum of a more concentrated form, so that it has been possible for large doses (*qua* immunisation units) to be administered. The average dose was 2000 units per injection, and the average number of injections was 2·3 per patient; but often that dose was considerably exceeded, and some cases received many injections. The rule has been to increase the dose the later the case has come under treatment, and it is pointed out that the only limit to the amount of "units" employed is the bulk of the serum. As compared with the experience of 1895 the returns of 1896 show that a greater proportion of children were submitted to the treatment, but that nevertheless the mortality was lower and the recovery-rate after tracheotomy improved. Some interesting facts are given as to the effects which are observed to ensue in patients treated with antitoxin. Thus the faucial swelling is diminished, there is lessening or cessation of nasal discharge, limitation of extension of the membrane and its earlier detachment, both in pharyngeal and laryngeal cases, besides general improvement in the patient's condition and a manifest prolongation of life even in cases that do end fatally. In Section II. of the report the same line of statistical inquiry is pursued in regard to post-scarlatinal diphtheria cases, which have the advantage of coming very early under observation and specific treatment. When we consider how high the mortality of such cases is usually estimated it is surely a striking proof of the efficacy of antitoxin that the rate amongst cases treated by it was only 5 5 per cent.

The medical superintendents thus sum up the results of their clinical and statistical observations. They find that the improved results in the diphtheria cases treated during the year 1896 are: (1) a great reduction in the mortality of cases brought under treatment on the first three days of illness; (2) the lowering of the combined general mortality to a point below that of any former year; (3) the still more remarkable reduction in the mortality of the laryngeal cases! (4) the uniform improvement in the results of tracheotomy at each separate hospital; and (5) the beneficial effect produced on the clinical course of the disease. "We have had, in fact, somewhat better results to record for 1896 than we had for 1895; and, in view of the extended experience gained during the past year, together with the additional facts concerning the post-scarlatinal cases for 1896, we feel that we are fully justified in the favourable opinion we expressed last year on the value of antitoxin in the treatment of diphtheria." They emphasise the importance of early administration and the trivial character of the secondary effects, maintaining their opinion that "in the antitoxic serum we possess a remedy of distinctly—we would now say much—greater value in the treatment of diphtheria than any other with which we are acquainted." The report is signed by J. MacCombie, R. M. Bruce, F. Foord Caiger, F. N. Hume, E. W. Goodall, C. E. Matthews, F. Meadows Turner, and F. Thomson. Dr. Gayton signs a separate memorandum, in which he notes the reduction in the mortality of the laryngeal cases and in the numbers of these requiring tracheotomy, but states that the results at the North-Western Fever Hospital were not such as to enable him to subscribe to all the conclusions of his colleagues. At the same time, illness prevented him taking much part in the supervision or treatment during last year. The appendix contains a detailed list of the fatal cases amongst those not treated with antitoxin, and also the statistics of each of the six hospitals.

ROYAL LONDON OPHTHALMIC HOSPITAL: LAYING OF THE FOUNDATION STONE.

THE neighbourhood of St. Luke's made a praiseworthy attempt to look gay on Friday afternoon, May 28th, when the Prince and Princess of Wales, accompanied by their daughter, Princess Victoria, attended at 162, City-road, E.C., for the purpose of laying the foundation stone of the new hospital. Punctually at 4 o'clock the Royal party arrived, attended by Lady Emily Kingscote and Captain Holford. They were received by a guard of honour with the band and colour of the regiment, mounted by the Honourable Artillery Company. At the door the Royal party were received by the president of the hospital, Sir John Lubbock, M P.; the chairman, Mr. H. P. Sturgis; the chaplain, the Rev. Prebendary Whittington; the honorary treasurer, Mr. J. Deacon, Mr. John Tweedy and Mr. E. Nettleship, and proceeded to the reception-room. The committee, accompanied by the medical staff, the architects, and the builder, then met their Royal Highnesses, with the Lord Mayor and Sheriffs, the Hon. Alban Gibbs, M.P., Mr. Percy Thornton, M.P., and others. The chairman presented the committee and medical staff to their Royal Highnesses, who afterwards moved forward to the platform. Miss Rosamond Ridley Smith presented a bouquet to the Princess of Wales and Miss Evelyn M. Tweedy one to the Princess Victoria.

Their Royal Highnesses having taken their places, Sir John Lubbock, whose voice was quite inaudible outside the canopy-covered daïs, where the stone was to be laid, addressed the Prince, giving a brief sketch of the events which have led to the present proceedings.

The Prince of Wales said: "Ladies and gentlemen,—As Sir John Lubbock has stated, this hospital was founded in 1804 by some gentlemen whose sympathies were aroused by the terrible sufferings of the army and navy belonging to the force in the Egyptian campaign under Sir Ralph Abercrombie. Many of the earliest patients were sailors and soldiers invalided home. It is a significant fact that while in this campaign in the early part of the century ophthalmia produced great ravages—out of a regiment of 700 men there were 636 cases, of whom 40 became blind of one eye and 50 blind of both—in the campaign in 1882, though there were 1800 severe cases of ophthalmia after Tel-el-Kebir, not one man lost his sight. This was entirely due to the excellent precautions taken. The Queen began her long connexion with the hospital in 1836, before she succeeded to the throne, by becoming patron. The importance of the hospital lies, not so much in the number of beds, which are only 100, as in the extraordinary number of out-patients, which are occasionally 550 in one morning. Altogether it is estimated that over a million different persons of the poorest class, all suffering from eye diseases, have been treated in the hospital since the Queen ascended the throne. The patients come from all parts of the United Kingdom and even from the colonies. Regarding its importance as a school of ophthalmic surgery, there is probably not one ophthalmic surgeon of eminence in the United Kingdom and the British colonies who has not studied in this hospital. Qualified medical practitioners come here from all parts of the world—from Canada, Judea, a large number from the United States, and even from Peru—to study ophthalmic science and surgery. The present buildings in Moorfields are over seventy years old, and are very deficient in the air, space, light, and quiet necessary for the patients, and there is often even insufficient standing room for the out-patients. The new hospital, which it is hoped will be soon completed, will greatly benefit sufferers from eye disease. The cost will, however, be very heavy and beyond the resources of the hospital committee unless they can succeed in obtaining a more liberal support than has been hitherto accorded to them. Therefore it gives the Princess, my daughter, and myself great pleasure to come here to-day, and I feel that in doing so I am performing an act which is deputed to me by Her Majesty the Queen. I know it is her great and earnest wish that the hospital may be very prosperous and successful in every way, and I think we may regard it as a fitting memorial of this special year when the Queen celebrates the sixtieth year of her reign."

The joint architects (Mr. K. D. Young and Mr. Bedells) and the builder (Mr. Gover) were then presented to His Royal Highness, who afterwards performed the ceremony and pronounced the stone to be "well and truly laid." The Bishop of London then offered prayer. Purses were subsequently presented to the Princess of Wales, and the chairman, Mr. H. P. Sturgis, and the Lord Mayor, vice-president of the hospital, thanked their Royal Highnesses for their presence.

Obituary.

JAMES GREIG SMITH, M.A., M.B., C.M. ABERD., F.R.S. EDIN.,

PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE, BRISTOL.

THE medical profession has sustained a very serious loss by the death of Mr. James Greig Smith, which took place after a very short illness from pneumonia on May 28th at his residence, 16, Victoria-square, Clifton, at the comparatively early age of forty-three years. The deceased was born at the village of Nigg, in Kincardineshire, and was educated at the neighbouring grammar school and University of Aberdeen. In 1873 he took his M.A. degree with the highest honours and the M.B., C.M., in 1876. After holding the office of house surgeon at the Royal Infirmary, Aberdeen, he was in 1876 appointed assistant house surgeon at the Bristol Royal Infirmary, where he subsequently became house surgeon and medical superintendent. He was elected surgeon at this institution in 1879, and from this date to the time of his death was one of the most active members of the staff, taking the keenest interest in all infirmary matters. During the early years of his Bristol life he gave special attention to pathology, and at that time published several able papers on Diseases of Bones, which clearly showed that love for investigation and intolerance of superficial work which characterised his whole career; his original research gained for him the distinction of election to the Fellowship of the Royal Society of Edinburgh. Starting as a general practitioner Mr. Greig Smith soon limited himself to surgery, and was in much request by medical men in the West of England and South Wales. As his reputation increased patients and practitioners gradually realised that the very best operative skill could be obtained in Bristol. His fame as a consultant was augmented by the publication of his book on "Abdominal Surgery," which is now accepted by the profession in England and abroad as a standard work, the sixth edition of which was in preparation at the time of his decease.

JAMES GREIG SMITH, M.A., M.B., C.M. ABERD., F.R.S. EDIN.,
PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE, BRISTOL.

From the time that Mr. Greig Smith joined the Bristol Medico-Chirurgical Society in 1877 he was a frequent contributor to its proceedings by papers, specimens, and discussion. He took a considerable share in the conception of the *Bristol Medico-Chirurgical Journal*, the first number of which was published in 1883, and he was its editor till 1892, having laid the foundation of its present success with remarkable literary skill.

He was from 1882 to 1884 an examiner in surgery at Aberdeen University, but the demands upon his time forced him to relinquish his journeys to Scotland. For several years he devoted much time and energy to the Professorship of Surgery at University College, Bristol. His skill as a draughtsman and his beautifully prepared museum specimens made his lectures at the medical school—the designs for which building he was largely instrumental in preparing—instructive and valuable to the large number of students who have had the benefit of his teaching. He was also largely responsible for the formation of the present magnificent medical library which may now rank among the first in the kingdom. His personality and force of character made a deep impression on those who came in contact with him, whether as students or colleagues. He will be particularly missed by all at the Royal Infirmary, where his opinion and advice were always eagerly sought. He was the pioneer of the separate ward scheme, which has proved so beneficial. Only a few days before his death he prepared plans for a new operation-room; these have been adopted by the infirmary authorities and will shortly be carried out. His general literary ability was well exemplified in his address on the Art of the Surgeon delivered at the annual meeting of the British Medical Association held in Bristol in 1894.

Both in speaking and writing Mr. Greig Smith's style was at once elegant, terse, forcible, and clear, and at the local meetings when he rose to speak the members expected something original, and were rarely disappointed. He always opposed in his well-framed sentences anything approaching an ill-formed opinion or an unsound argument. Mr. Greig Smith in his home life was a man of simple habits, and in his spare hours devoted himself to modelling in clay or other artistic pursuits. He was greatly devoted to the pleasures of a country life, and for this purpose took a shooting-box near Bristol, and became a good shot, an expert fisherman, and an enthusiastic golfer. His wife and only child, a daughter, survive him.

His remains were buried at Redland Green Cemetery on June 1st. The funeral was attended by most of the medical men of Clifton and Bristol, and by medical practitioners and friends from neighbouring towns who had come to pay their last tribute of respect and gratitude to the departed surgeon. Besides these were many nurses and patients, all showing how deeply they felt the loss they had sustained by the inexorable hand of death.

FREDERICK ALCOCK NIXON, M.R.C.P., F.R.C.S. IREL.

MR. F. A. NIXON, who died from apoplexy at his residence in Dublin on May 23rd, had acquired a considerable reputation as a surgeon, and the news of his untimely death came as a painful shock to his many friends. He received his medical

Hosted by Google

education at the Ledwich School and Mercer's Hospital, and became a Licentiate of the Royal College of Surgeons in Ireland in 1870, as well as of the Royal College of Physicians of Ireland in the following year. He then entered the Medical Department of the Navy, and was at sea for some time, but he made only a short stay in the service, and returned to Dublin with a view to engaging in the more congenial duties of a teacher. In 1876 he was admitted to the Fellowship of the College of Surgeons, and in 1880 to the Membership of the College of Physicians. For many years he was attached to the Ledwich School as lecturer on surgery and anatomy, and when this school was amalgamated with that of the College of Surgeons in 1889 he became one of the professors of surgery, an appointment which he retained until his death. For a long time he had a seat on the Council of the College, and was also a member of the managing committee of the Conjoint Examination Board. Many years ago he was appointed surgeon and lecturer on surgery in Mercer's Hospital, the perturbed state of which institution was of late a cause of much anxiety to him. At the time of his death Mr. Nixon was only in his forty-seventh year. Those who knew him best feel it to be a real misfortune that a career so full of promise should have closed thus prematurely.

CHARLES ALEXANDER LOCKHART ROBERTSON, M.D. CAMB. AND ST. AND., F.R.C.P. LOND., &C.

DR. LOCKHART ROBERTSON, whose death at Exmouth on May 18th has been already announced in THE LANCET, was one of our most distinguished alienist physicians. His father was a surgeon and lecturer in Edinburgh, and he received his medical education in that city, taking in 1845 the degree of M.D. at St. Andrews University and the Licence of the Royal College of Surgeons of Edinburgh. He then entered the Army Medical Service, and obtained his first insight into lunacy practice while assistant surgeon at the Military Lunatic Asylum at Yarmouth. In 1849 he was admitted a Fellow of the Royal College of Physicians of Edinburgh. After five years' service at Yarmouth, he proceeded to Cambridge University and once more engaged in medical study, taking the M.B. degree in 1853 and the *ad eundem* M.B. at Oxford in 1857. He then settled in London and joined the newly-formed Medico-Psychological Association, of which he was for several years honorary secretary and subsequently president. More than this, when Sir John Bucknill retired from the editorship of the *Journal of Mental Science*, Dr. Lockhart Robertson, in conjunction with Dr. Maudsley, succeeded him—an appointment which was in several ways beneficial both to the journal and to the Association. A wider field of usefulness was opened to him in 1859, when he was appointed the first medical superintendent of the new Sussex County Asylum at Hayward's Heath, and soon showed that judicious treatment and careful management could accomplish much in the way of brightening the life of the insane. His earnestness and success in this work, which thenceforth became for him an absorbing pursuit, were universally recognised, and the Hayward's Heath Asylum speedily acquired the reputation of being a model institution. He continued at the head of it until 1870, when his prominence in this special department induced Lord Chancellor Hatherley to appoint him to the vacant office of Visitor of the Chancery lunatics—patients scattered throughout the various asylums in England whose affairs have at some time or other come under the cognisance of the Court of Chancery. This post he held for twenty-five years, resigning only in January, 1896, when he was seventy years of age. Dr. Lockhart Robertson was a man of much culture and many accomplishments; he had a very large circle of friends and acquaintances, and during his active years was a prominent figure in social life. His wife was the daughter of Colonel Rochfort of the Indian army.

CHARLES HAWKES MARWOOD MULES, M.R.C.S. ENG., L.S.A.

THE death occurred, at his residence, Ilminster, Somerset, on May 23rd, of Mr. C. H. M. Mules, at the advanced age of eighty-four years. The deceased, who was educated at Middlesex and University College Hospitals, took the qualifications of M.R.C.S. Eng. and L.S.A. as long ago as 1836, and had one of the largest country practices in Somersetshire, to which he joined several public appointments. He was popular, not only with his patients, but amongst a very large circle of friends, and, although in his eighty-fifth year, until quite recently was a frequent follower of the hounds. His death will be deeply regretted by many in the West of England.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent medical man is announced:—Dr. Louis Deroubaix, of Brussels, where he had been Professor of Anatomy for fifty-seven years. He was honorary president of the College of Brussels Practitioners, private medical adviser to the King, and Grand Officer of the Order of Leopold. While surgeon to the Brussels hospitals he devised and performed many important new operations and published a large number of surgical papers. He was in his eighty-fifth year.

THE BATTLE OF THE CLUBS.

THE NOTTINGHAM MEDICAL UNION.

THE first annual meeting of the Nottingham Medical Union was held on the 26th ult. In their report the Council state that the subjects that have especially occupied the attention of the Union during the year are: Rate of Payment in Clubs; Medical Aid Societies combined with Insurance Societies; and Hospital Abuse.

In regard to the first-named subject the Union succeeded in obtaining a practically unanimous agreement of the medical men in Nottingham not to take new clubs after Jan 1st, 1897, for less than 4*s*. per annum. This agreement has, the Council believe, been loyally adhered to. With regard to medical aid societies combined with insurance societies, the objections it is stated in Nottingham resolve themselves into two: (1) canvassing the patients of other medical men on behalf of their own medical officers, sometimes leaving lists of those officers at the houses visited; and (2) canvassing and accepting as members persons whose means should enable them to pay ordinary medical mens' fees or who are chronic invalids. The threat of action by the Union in September, 1896, caused the London and Manchester Insurance Company to offer to amend its ways by withdrawing the printed list of its medical officers and by forbidding its agents to accept persons of good financial position. The local manager of the Liverpool Victoria Society also assured the President of the Nottingham Medical Union that his society did not wish to have, and would refuse, these two classes of persons. It was accordingly resolved to give time for these reforms to be carried out, but, with the exception of the withdrawal of the printed list, there seems to have been no real improvement in the methods of these societies.

The Council regret the lack of support which they receive from the medical profession as a body with regard to their fight against the medical aid and insurance societies, and no successful stand can be made until the profession is consolidated throughout the whole country. To effect this consolidation not merely must unions be formed in every district, but the coöperation of the licensing bodies and General Medical Council must be obtained. It is only, however, by the repeated agitation of the working members of the profession that they will be induced to act.

In addition to the clubs and medical aid societies in Nottingham there exist a number of "sick and annual clubs," meeting at public-houses, which appear open to grave criticism. These will probably form the subject of inquiry in the ensuing year.

The Council have appointed a committee to deal with the subject of hospital abuse, but investigation is still in an early stage. The problem is difficult and delicate, but it is hoped that even if a perfect solution is not found, yet a considerable improvement may be obtained. The provision of suitable accommodation, nursing and medical or surgical care for persons of the middle class who are seriously ill and may need operation has also come under the consideration of the Union. There are many persons of moderate means who neither desire nor ought to become patients in a charitable institution, whose homes are yet quite unfit to be the scene of grave operations, and who may only be able to pay moderate fees for surgical and nursing attendance. To such

Hosted by Google

persons the establishment of a nursing home or private hospital, where they could be lodged and boarded at rates varying according to the privacy and accommodation demanded, where they would be under the care of their own medical man at a rate of fees arranged by mutual agreement and where they would be attended by trained nurses, would be a boon.

THE ROYAL MILITARY TOURNAMENT.

THE sanitary arrangements at the Royal Agricultural Hall, Islington, when occupied by the troops taking part in the Royal Military Tournament, have been described in these columns on so many occasions that it is hardly necessary to refer to them again in detail. The building is ill adapted for the housing of troops, but under the able advice of Surgeon-Major Alexander, of the Coldstream Guards, who is assisted by Surgeon-Major James, A.M.S., the sanitary conditions of the hall have been made as perfect as the circumstances will allow. Four new ventilators have been constructed in the roof of the building, and a great improvement has been made in the ventilation of the arcade by the construction of sixteen swinging "lights," eight on either side. This part of the building, where many cubicles are placed, has hitherto suffered greatly from want of fresh air, and though there is still room for improvement, we are glad to note that some of our suggestions have taken practical shape. It is a pity, however, that those in charge of the Tournament cannot see their way to remove it to more commodious premises. As we have said, the building has no doubt been made as sanitary and as comfortable for the troops as circumstances will allow, but apart from the fact that some 870 men and 400 horses here find a home—far too large a number for the amount of accommodation, we think—the building is altogether unworthy of what has now become, perhaps, one of the most important naval and military gatherings of the year. We say most important advisedly, because it is evident from the enthusiasm of the public that the Royal Military Tournament has become one of the greatest factors in popularising the navy and army. To prove this would require too long a digression, but it will, we believe, be generally admitted.

The watchword of the present committee seems to be "economy." For the first time the catering for the troops is done by the military authorities themselves, and with the most satisfactory results. The cost per man is 1*s.* 3*d.* per diem, and the food supplied is greatly appreciated by the men.

The work of economy is seen, too, in other directions. The scenery, which in previous years has formed a sort of background to the combined display of all arms, has been dispensed with, and in its place there have been erected a number of seats which probably bring in not less than £200 per night. This of course, adds greatly to the coffers of the participating charities, but decreases the amount of air space in the building.

With regard to the medical aspect of the arena little is to be said. The performance which has in it the greatest element of danger, though not perhaps so apparent to the eye as in other performances, is the trotting and galloping practice by the artillery. There is, of course, considerable risk to the men engaged in the practice, but in one respect there is more risk to the spectators. Should by chance the wheels of the gun carriage strike against the "obstacles" through which the wheels pass and splinter the wood there is every chance of it being hurled through the air and striking the spectators. Galloping by the artillery under these circumstances should be eliminated from the programmes; the "trotting" is quite exciting enough, as the tremendous applause which greets the successful avoiding of the obstacles demonstrates. Of the condition of the stables, which are under the charge of Veterinary-Major Rowe, A.V.D., there is nothing to complain.

Upon the whole we can congratulate Colonel F. Lorn Campbell, the Commandant; Major F. Lloyd, the treasurer; Lieutenant-Colonel E. W. D. Ward, C.B., the honorary secretary; and the other members of the staff who have assisted in the organisation of this year's tournament.

The Tournament will close on June 10th, and those desirous of viewing one of the best sights of the year should book seats at once, as the hall is filled to overflowing at each performance.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6226 births and 3492 deaths were registered during the week ending May 29th. The annual rate of mortality in these towns, which had been 16·5 and 17·2 per 1000 in the two preceding weeks, declined again last week to 16·6. In London the rate was 14·9 per 1000, while it averaged 17·7 in the thirty-two provincial towns. The lowest death-rates in these towns were 6·9 in Croydon, 9·5 in Cardiff, 12·5 in Swansea, and 12·9 in Portsmouth; the highest rates were 22·1 in Burnley, 23·2 in Gateshead, 23·6 in Bolton, 24·0 in Sheffield, and 28·6 in Salford. The 3492 deaths in these towns included 355 which were referred to the principal zymotic diseases, against 341 and 357 in the two preceding weeks; of these, 111 resulted from whooping-cough, 97 from measles, 57 from diphtheria, 39 from diarrhœa, 32 from scarlet fever, and 19 from "fever" (principally enteric), No fatal case of any of these diseases was recorded in Croydon; in the other towns they caused the lowest death-rates in Newcastle-upon-Tyne, Bradford, Bristol, and Leeds, and the highest rates in Manchester, Bolton, Oldham, and Salford. The greatest mortality from measles occurred in West Ham, Oldham, Birkenhead, Bolton, Manchester, and Salford; from scarlet fever in Huddersfield; and from whooping-cough in Plymouth, Halifax, Manchester, and Salford. The mortality from "fever" showed no marked excess in any of the large towns. The 57 deaths from diphtheria included 36 in London, 4 in Birmingham, 3 in Leicester, and 3 in Burnley. No fatal case of small-pox was registered last week in any of the thirty-three large towns. There were 12 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, May 29th, against 11, 14, and 13 at the end of the three preceding weeks; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2546, against numbers increasing from 2380 to 2508 on the four preceding Saturdays; 278 new cases were admitted during the week, against 231, 239, and 311 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 198 and 220 in the two preceding weeks, declined again last week to 196, and were 108 below the corrected average. The causes of 49, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Oldham, Bradford, Sunderland, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Swansea, Birmingham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 20·7 to 22·3 per 1000, declined again to 21·7 during the week ending May 29th, but exceeded by 5·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·2 in Perth and 18·9 in Paisley to 26·9 in Edinburgh and 30·4 in Leith. The 648 deaths in these towns included 34 which were referred to whooping-cough, 24 to measles, 21 to diarrhœa, 5 to diphtheria, 4 to "fever," and 3 to scarlet fever. In all, 91 deaths resulted from these principal zymotic diseases, against 102 and 110 in the two preceding weeks. These 91 deaths were equal to an annual rate of 3·1 per 1000, which was 1·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 29 and 35 in the two preceding weeks, were 34 last week, and included 18 in Glasgow and 9 in Edinburgh. The deaths referred to measles, which had increased in the three preceding weeks from 29 to 49, declined again last week to 24, of which 16 occurred in Edinburgh, 4 in Glasgow, and 3 in Leith. The 5 fatal cases of diphtheria corresponded with the number in the preceding week, and included 3 in Glasgow and 2 in Edinburgh. The deaths referred to different forms of "fever," which had been 1 and 3 in the two preceding weeks, further rose to 4 last week, all of which were registered in Glasgow. The deaths

Hosted by Google

from diseases of the respiratory organs in these towns, which had been 108 and 135 in the two preceding weeks, declined again to 128 last week, but were 19 above the number in the corresponding period of last year. The causes of 45, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 33·7 to 27·3 per 1000, rose again to 28·3 during the week ending May 29th. During the past eight weeks of the current quarter the death-rate in the city has averaged 30·7 per 1000, the rate during the same period being 16·2 in London and 26 6 in Edinburgh. The 190 deaths registered in Dublin during the week under notice showed an increase of 7 upon the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against numbers declining from 41 to 15 in the five preceding weeks; of these, 5 resulted from measles, 4 from diarrhœa, 3 from scarlet fever, 2 from whooping-cough, 1 from "fever," and not one either from small-pox or diphtheria These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rate during the same period being 1·6 in London and 5·2 in Edinburgh. The fatal cases of measles, which had declined from 19 to 5 in the five preceding weeks, were again 5 last week. The deaths referred to whooping-cough, which had been 6 in each of the two preceding weeks, declined to 2 last week. The mortality from "fever" was below that recorded in any recent week. The 190 deaths in Dublin last week included 36 of infants under one year of age, and 51 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons exceeded those recorded in any recent week. Seven inquest cases and 6 deaths from violence were registered; and 68, or more than a third, of the deaths occurred in public institutions. The causes of 14, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL MAURICE KNOX retires on retired pay.

Surgeon-Captain Thompson has been ordered to the Curragh, and Surgeon-Lieutenant-Colonel Mapleton has been ordered to the Station Hospital, Shorncliffe. Surgeon-Major R. J. McCormac joins at Woolwich.

INDIA AND THE INDIAN MEDICAL STAFF.

Surgeon-Captain Bedford (Bengal) is appointed to officiate as Chemical Examiner and Professor of Chemistry in the Medical College, Calcutta, during the absence on furlough on medical certificate of Surgeon-Major Waddell, or until further orders. Surgeon-Lieutenant-Colonel W. Barren and Brigade-Surgeon-Lieutenant-Colonel S. M. Salaman have respectively delivered over and received medical charge of the Yerrowda Central Prison. Surgeon-Major Pank has assumed medical charge of the Jeypore Residency from Surgeon-Major Harington.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeon Bernard Renshaw to the *Pembroke*. Surgeons: Francis J. Barter to the *Medusa;* Arthur W. B. Livesay to the *Pembroke;* and Harold G. T. Major to the *Blenheim*.

VOLUNTEER CORPS.

Artillery: 2nd Cinque Ports (Eastern Division, Royal Artillery): Howard Marshall, M.B, to be Surgeon-Lieutenant. *Royal Engineers:* 2nd West Riding of Yorkshire (Leeds): Surgeon-Captain James William Henry Brown resigns his commission, and is appointed Lieutenant. *Rifle:* 2nd Volunteer Battalion the East Yorkshire Regiment: Surgeon-Lieutenant William Albert Wetwan resigns his commission, and is appointed Second Lieutenant.

THE LATE GRECO-TURKISH WAR.

The additional Parliamentary papers that have been published are not, we feel bound to say, calculated to raise our conception of the motives and conduct of Greece, or of the wisdom of the Hellenic Government in adopting a war policy and undertaking a campaign against Turkey in opposition to the advice of the rest of Europe. The Greeks were quite unprepared for war against so formidable an adversary as Turkey. The military, commissariat, sanitary, and medical departments of the Greek army seem to have been badly organised and quite inadequate to their self-imposed task, and the consequence has been that, not only have they been severely defeated, but an incalculable amount of unnecessary suffering has been inflicted by the war upon the military forces and agricultural population of Greece. By their precipitate action in forcing on this foolish war they have rehabilitated the Sultan's power and imposed a most difficult task on the Powers friendly to them, when their real strength was, like the Israelites of old, to have sat still. All independent accounts agree in stating that the Turkish war and hospital organisation and arrangements were superior to those of the Greeks. The English hospital at Chalcis is stated to be excellent. The Queen and Princess Sophia were expected to visit and inspect the hospital and its arrangements. The total number of wounded admitted to the Athens hospitals was 2363 Of these, 836 are still under treatment, 31 have died, and the rest have been discharged.

AMBULANCE SERVICE ON JUBILEE DAY.

The London companies of the Volunteer Medical Staff Corps are to be requisitioned to augment the Medical Staff Corps in view of the possibility of accident on June 22nd. Mr. Arthur S. Dale, of the St. John Ambulance Association, has issued an appeal to the public in view of the large number of fits and accidents which may occur on that day. As it will be inconvenient to treat such cases in the road, and as ambulance stations are too few and far between, householders on the line or contiguous to the route who can place a back room at the disposition of the ambulance service will confer a benefit on the afflicted; and if hotel proprietors and licensed victuallers will afford ice for ambulance cases it will be most serviceable in the alleviation of suffering. Offers of help should be made to the Brigade Chief Superintendent, Mr. W. Church Brasier, of St. John's-gate, Clerkenwell.

THE EXAMINATIONS FOR NAVAL SURGEONS.

The undermentioned gentlemen, who competed on the 17th inst. and following days at Examination Hall, Victoria Embankment, for appointment as surgeon in the Royal Navy, have been granted commissions:—

Brigade-Surgeon McLeod, retired from the Indian Medical Service, has been selected for appointment as Professor of Clinical and Military Medicine at the Army Medical School, Netley, to succeed Deputy-Surgeon-General Cayley.

THE HEALTH OF THE ARMY IN INDIA.

The *Pioneer Mail* of May 13th states that the Simla committee on the contagious diseases question did not finish its report early enough to enable the Indian Government to frame its dispatch to the Secretary of State in time for the mail, but that it will probably be sent by the next. Meanwhile, some additional Parliamentary papers—one of a statistical nature on the prevalence of the disease in the Army for many years past, and embracing periods when the Acts were in force and since their repeal—have been issued. When the proposals of the Indian Government have been received at the India Office we may expect that the question will again be taken up in earnest.

THE PLAGUE IN INDIA.

We are extremely glad to learn from the Anglo-Indian papers and the telegraphic report of the Governor of Bombay to the Secretary of State for India that bubonic plague is fast disappearing in Bombay. The authorities are still, very properly in our opinion, exercising the powers conferred upon them by the Epidemic Diseases Act, and there are no signs of relaxation in their efforts to eradicate the disease from the whole Presidency.

ENTERIC FEVER IN INDIA.

We regret to learn that enteric fever is prevalent at Lucknow, the Duke of Cornwall's Light Infantry being the

Hosted by Google

chief sufferers. The outbreak among the troops at Subatha has ceased. A provisional scheme for the temporary water-supply of the station has been adopted pending the completion of the larger project at present in hand.

DR. KOCH IN INDIA.

The *Times of India* of May 15th states that Dr. Koch has received telegraphic instructions from the German Government to remain in India and continue his investigations and experiments in regard to rinderpest, and in all probability he will proceed to Bengal shortly, where rinderpest is said to prevail.

Surgeon-Colonel W. F. Stevenson, Professor of Military and Clinical Surgery at the Army Medical School, Netley, will attend as a representative of the British Army at the International Medical Congress to be held in Moscow from Aug. 19th to Aug. 26th.

Correspondence.

"Audi alteram partem."

"THE APPROPRIATION OF FINES UNDER THE MEDICAL ACT."

To the Editors of THE LANCET.

SIRS,—In the leading article in THE LANCET of May 22nd upon the important subject of the alienation of penalties from the General Medical Council, in *re* prosecutions under the Medical Act, you state that "in all other parts of the country other than the metropolis the fines go to the General Medical Council." This is, unfortunately, not the case. Certain boroughs claim, and have claimed successfully, under local Acts the penalties inflicted upon persons convicted under the Medical Act, 1858. The matter has been brought to the knowledge of the General Medical Council by the Medical Defence Union lately, and it is to be hoped that some legal steps will be taken to prevent the alienation in future. If nothing be done by the General Medical Council, prosecutions in the country will be as rare as they are in the metropolis, and for the same reason. I may mention that it was at the instigation of the Medical Defence Union that the question was raised by Dr. Glover in May, 1891, with the result that a deputation was sent to the Home Secretary, as detailed by you.—I am, Sirs, yours faithfully,

A. G. BATEMAN,
May 21st, 1897. General Secretary, Medical Defence Union.

"DEFECTIVE" CHILDREN IN SCHOOLS.

To the Editors of THE LANCET.

SIRS,—The leading article on Ophthalmia in the Liverpool Schools which appeared in THE LANCET of May 15th appeals very strongly to all those who have anything to do with elementary education in our poorer districts. Your pregnant declaration that "in a large proportion of cases there can be little doubt that overcrowding, dark and ill-ventilated rooms, damp soil, and insufficient diet are very efficient agents in developing and in promoting the extension of the disease" is capable of wide application. In London especially both teachers and managers of elementary schools are continually hampered in their educational work by the exact conditions you mention, which unfortunately apply to a large proportion of the children of the poor. The result is that in every school in the poorer localities there are a number of cases of "defective" scholars, who, owing to general home neglect and bad nutrition, are physically incapable of receiving any advanced instruction. Of the children who attend the London Board Schools nearly 60,000 go to school breakfastless every day, and a much larger number are ill-clad and ill-nourished. Fortunately, the Education Department is taking this matter in hand, and special arrangements will now have to be made for grouping these defective children together, providing them with a special teacher, and giving them the most suitable instruction for their special needs. To-day I was in a school which consists largely of the children of casual dockers, and 10 per cent. of the scholars had to be scheduled for this special treatment. But, unfortunately, the causes of defect will to a large degree remain untouched by school care, while the defective homes exist under our present social system. My object in writing to you is to humbly point out that no greater service could be performed by the medical profession to the children, to the nation at large, and to the coming generation than the using of their powerful and unequalled influence to assist in raising such a conscience and opinion in the community as will ere long make the conditions which now literally manufacture defective children things of the past.

I am, Sirs, yours faithfully,

HERBERT BURROWS,
London Board School Manager.
Aberdeen-road, N., May 19th, 1897.

"URIC ACID IN THE BLOOD."

To the Editors of THE LANCET.

SIRS,—Dr. Luff has missed the point of my objection to his experiments. If he will allow me to correct him, he stated in the Goulstonian Lectures that when he added known quantities of uric acid to blood the quantity which he extracted was estimated by the Gowland Hopkins method to be from 80 to 87 per cent. In his description of this method he says: "1 milligramme [should be] added to the final result for each 15 c c. of the filtrate present—this need never be more than 20 to 30 c.c." In the absence of any statement to the contrary, the assumption is that the known quantities were suitable for estimation by this method—i.e., from 20 to 40 milligrammes, and there is no evidence in the lectures that quantities ranging from $\frac{1}{10}$ to $\frac{1}{2}$ milligrammes, added to 500 c.c. of blood, were subsequently extracted and proved either by the Gowland Hopkins method or the murexide test. The extreme delicacy of the murexide test, to which Dr. Luff calls my attention, ought to enable him to prove his point without question. If he adds $\frac{1}{30}$ milligramme to 500 c c. of blood he can (so he says in effect) extract $\frac{1}{100}$ milligramme, which will give the murexide reaction. But no such experiment is recorded. With regard to the "abundant quantity" of uric acid in bird's blood, it would certainly be more satisfactory to state the necessary and sufficient proportion on the hypothesis that uric acid is derived from blood, as it would show at once whether the methods adopted were suitable for the purpose. Dr. Luff has undertaken the difficult task of proving a negative, and before accepting his conclusion one must know what the "known quantities" were and how they compare with the necessary and sufficient quantities in animals and birds.

I am, Sirs, yours faithfully,

Norwood, May 22nd, 1897. DONALD F. SHEARER.

"OPHTHALMIA IN LIVERPOOL."

To the Editors of THE LANCET.

SIRS,—I have obtained liberty to send you the following letter, which I received from Professor Jacob last week. I hope you will be able to insert it as a very interesting and able contribution to the question of granular lids.

I am, Sirs, your obedient servant,

W. ALEXANDER.
Rodney-street, Liverpool, May 25th, 1897.

"Ely-place, Dublin, May 23rd, 1897.

"DR. ALEXANDER.

"DEAR SIR,—An editorial in THE LANCET informs me that in a controversy with Mr. Fuller you have resisted the assumption that granular ophthalmia is, in its nature and in fact, an unquestionably contagious disease. It is, perhaps, well that I have seen neither Mr. Fuller's report nor your reply, for I am thus enabled to give a perfectly independent opinion on the subject, and that opinion is strongly in support of the view attributed to you. If there be any eye disease respecting which Irish ophthalmologists may claim to have special knowledge it is this. I see at my extern about 3000 cases annually, and I do not hesitate to say one-third of these are cases of granular ophthalmia or its sequelæ. Without asserting that such cases are altogether non-contagious, I say that my experience is dead against the contagion theory. Upon this point I note that the most ardent apostles of contagion and THE LANCET itself venture no further than to express their belief that a specific contagium must exist somewhere and will be found sooner or later; and Dr. Stephenson, in his recent monograph on the subject, admits that the announcements from time to time that such contagium had been identified 'have not stood the test of experience.' I am, from practical experience, somewhat sceptical of the existence of such specific agency, because I see scores of instances in which one or two members of a family suffer without any extension to the others and scores of cases in which one eye is affected without any extension to the other. Perhaps more striking evidence is afforded by the fact that the surgeons, nurses, and students of eye hospitals are, so to speak, up to their elbows in the various forms of granular ophthalmia

Hosted by Google

and in the closest contact with the discharges from such eyes, and yet it is the rarest occurrence for any one of them to suffer from even a transient conjunctivitis. I have myself manipulated, shall I say, tens of thousands of granular ophthalmias in one or other form, and as yet I have been, happily, entirely free from any such disease.

"My purpose in thus writing is to enforce the suggestion that the fashionable isolation remedy is a stupendous mistake and that the true cause of this decimating disease and its remedy are in danger of being forgotten in our anxiety to find means of prevention. I subscribe to the statement of THE LANCET that 'overcrowding, dark and ill-ventilated rooms, damp soil, and insufficient diet' are very efficient agents in developing the disease. In fact I believe that they are, practically, the only agents and that contagion has but a small influence. The *sequitur* of my argument is that the system of aggregating large numbers of children in big isolation hospitals is good only so far as it removes such children from insanitary surroundings and not at all because it isolates them, which, indeed, it does not do. I hold that if these children could be boarded out in farm houses or could be otherwise provided with fresh air, nutrient diet, and tonic medicine they would get well, with the assistance of a little local treatment, months in advance of the (so-called) isolated patients. I will go so far as to say that I never saw a case of granular conjunctivitis in its primary stage which I could not cure by such means and without any serious danger of infection to the persons with whom they might be boarded out.

"Yours very truly,

"ARCHIBALD HAMILTON JACOB, M.D., F.R.C.S.I.,
"Professor of Ophthalmology, Royal College of Surgeons in Ireland,
Ophthalmic Surgeon to the House of Industry Hospitals,
Dublin."

"THE HOSPITAL REFORM ASSOCIATION: REPORT OF THE COMMITTEE APPOINTED TO INQUIRE INTO THE WORKING OF THE SPECIAL HOSPITALS OF LONDON."

To the Editors of THE LANCET.

SIRS,—In a report published by the Hospital Reform Association on certain of the London hospitals statements are made with regard to the London Throat Hospital which have been brought before the notice of the medical committee of that institution, and on whose behalf I am instructed to write to you as follows:—1. The medical committee protest most emphatically against the manner in which this incorrect information has been obtained. Two gentlemen, it appears, came to the hospital without any permission or invitation from the committee or medical staff or from any subscriber, and without having given any notice of their advent they asked to see the secretary. It now appears they were medical men and their conduct can only be characterised as most discourteous to their professional brethren, and also to the governing body of the institution. 2. They asked various questions, and our secretary absolutely denies having given any such information as they allege to have received, and which is contained in their "Statements and remarks"—i.e., "as to patients' means." They state this is "left to visiting staff"; "a proper system of inquiry is absent." This allegation on their part is wholly at variance with the facts. A most careful inquiry is made into the means and position of each patient by a person especially appointed and paid for discharging that duty. 3. As to beds. The gentlemen who visited the hospital were informed that at that very time of their visit new wards were in course of preparation and almost completed for the reception of fifteen patients, and it was most unfair of them in the face of that information to state there were only five beds. The medical committee trust that you will at once take steps to have these erroneous statements withdrawn, and the facts correctly stated.

I am, Sirs, yours faithfully,

HERBERT TILLEY, M.D. Lond.,
May 31st, 1897. Honorary Secretary to Medical Committee.

THE HOSPITAL REFORM ASSOCIATION: AN APPEAL.

To the Editors of THE LANCET.

SIRS,—May I be allowed to appeal to all those members of the profession who are sincerely desirous of seeing the administration of medical relief in our hospitals restricted to those who are really in want of it to help the Association with funds? The memory of most men is short, and therefore I may be pardoned for reminding them that the Association has placed itself in communication with every hospital in England and Wales, and has held meetings of the profession in London, Birmingham, and Manchester. Only those who have had actual experience in the work of organisation can realise the cost of holding such meetings as we have held. We may perhaps be pardoned for assuming that we have done any real good, but unless I am misinformed the general hospitals of the metropolis have already determined to take steps to bring about a reform of their out-patient and casualty departments. My council believe that they are engaged in a righteous crusade, and they are endeavouring to accomplish their objects without resorting to extreme measures. As far as I am aware, no steps have been taken which are in the least likely to injure the name and good fame of our great charitable institutions. To restrict their use for whom they were originally intended, and to make them *more useful* to those persons who are in need of their aid, has been the aim of the Association to which I have the honour to belong.

I am, Sirs, yours faithfully,

T. GARRETT HORDER, Honorary Secretary.

Cardiff, May 28th, 1897.

"ON CERTAIN SYMPTOMS OF SPINAL CORD AFFECTION IN BICYCLE RIDERS."

To the Editors of THE LANCET.

SIRS,—In reference to two articles in THE LANCET of April 17th and May 15th on the above subject I beg leave to make the following remarks. The symptoms in question are not due either to cycling *per se* or to the "wedge-shaped article ..... called a saddle." They are owing either to the distance between the saddle and the pedals being too great, or to the saddle not being placed horizontally, or to the handlebar being too low. In all these cases the body is bent too much forward and is no longer supported by the tuberosities of the ischium as it ought to be, but by the perineum. When the faulty position of the saddle is corrected the symptoms complained of will certainly disappear.

I am, Sirs, yours truly,

J. HARPÖTH,
Assistant Physician, Frederiksberg Hospital,
May 23rd, 1897. Denmark.

THE OXYGEN TREATMENT OF ULCERS.

To the Editors of THE LANCET.

SIRS,—Having recently had an opportunity of watching the oxygen treatment of ulcers at Netley, and comparing the results with those of an ordinary method, I was not a little astonished to see a report from the assistant professor of bacteriology, who not only had nothing to do with the treatment of the cases, but had not even taken the usual course of seeing and consulting the medical officer in charge. The official report being of a confidential nature I cannot enter into particulars, but feel bound to state that, apart from the bacteriological aspect of the question, Surgeon-Major Semple's facts and inferences are grossly inadequate and misleading.—I am, Sirs, yours faithfully,

Netley, May 31st, 1897. M. KELLY, Surgeon-Major, A.M.S.

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—In this eventful Jubilee year many of us are doubtless hampered with special appeals of all kinds; but we shall all agree that those of our poorer brethren who have fallen in the battle of life, and who are helpless and sore stricken, are especially deserving our sympathy and help at the present time. The funds of the British Medical Benevolent Society are now at a very low ebb, and have for some time been quite inadequate to the relief of the large and increasing number of cases, many of which are very distressing. A glance at the last report will show the excellent work done by the Fund; but how piteous are the stories of those 158 cases which were relieved, representing every kind of trouble, affliction, and distress which may at any time befall any one of us; and how much more could be accomplished in the way of relief with a little additional help from the profession. Surely at such a time our hearts will respond to an appeal for thank-offerings, if only for our own good health and prosperity. It should be especially noted that the applicants for relief are spared all the trouble and expense of canvassing or the pain of publicity, and that the cases are most carefully investigated by the committee, while no fund could be more

Hosted by Google

judiciously and economically administered. It would relieve the anxiety of the treasurer and the officers of the society, and add greatly to the zest of our own enjoyment of all the good things we have and which are awaiting us, if at this time of general rejoicing we could gladden the hearts of our poorer brethren and sisters by a substantial addition to the fund. It is a great privilege to be able to help others at any time, and this is an unparalleled occasion which can never return in our time. From the report we learn that donations and subscriptions—especially the latter—will be gratefully received by the treasurer, Sir W. Broadbent, Bart., 84, Brook-street, W.; by Dr. Samuel West, honorary financial secretary, 15, Wimpole-street, W.; by Mr. Joseph White, honorary secretary for cases, 6, Southwell-gardens, Queen's-gate, W.; or by the London and County Bank, 21, Hanover-square, W.

I am, Sirs, yours faithfully,

May 24th, 1897. BIS DAT QUI CITO DAT.

"A QUESTION OF COURTESY."

To the Editors of THE LANCET.

SIRS,—As one of the ladies upon whose want of courtesy you comment, I must request you kindly to insert a few lines with regard to the misleading letter published in THE LANCET of May 8th, written by Dr. F. D. Miller, and headed "A Question of Courtesy." That letter asserts that a lady guardian took Miss Annie McCall, M.D. Bern., and also a district nurse, to see a poor patient of Dr. Miller's without communicating with him. Dr. Miller, having already written to the lady guardian on the subject, was acquainted with the fact that the lady guardian was unaware that he had ever attended this patient, and, so far from taking Dr. A. McCall to visit the patient, she had never known of or seen Dr. A. McCall until after she had visited the poor woman. Then as to the district nurse, the lady guardian has never seen her and never "took her" or asked her to call on Dr. Miller's patient. Dr. Cooper Smith, D.D.'s, letter in THE LANCET of May 29th exonerates the district nurse, and will, with the above statement, show that it is hardly fair to pass so severe a sentence as is contained in your editorial comment until your motto, "Audi alteram partem," has been fulfilled.

I am, Sirs, your obedient servant,

E. EDITH MITCHELL,

Down Grange, Basingstoke, May 31st, 1897. Lady Guardian.

"PROFESSIONAL EXCLUSIVENESS IN ITALY."

To the Editors of THE LANCET.

SIRS,—Will you allow me to point out that Mr. J. Eyre is not quite correct in one of his statements which appeared in THE LANCET of May 22nd? He says that "foreign medical men can practise in the United Kingdom without restriction, but unless they are registered they cannot recover their fees by legal process or give medical evidence in courts of law, or hold public medical offices"; he ought to have added that they cannot sign a certificate of death. This is a most important point, as that restriction alone effectually prevents a non-registered foreigner from practising in England. The question of reciprocity with foreign countries is a difficult one, because, if it were granted, the advantages would be very much on the side of England, even if the effects of reciprocity extended to the colonies, which would probably not be the case.

I am, Sirs, yours faithfully,

May 31st, 1897. XENOS.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

XI.—NOTTINGHAM.[1]

Action of the Nottingham Medical Union.—Appeal for Information to all Members of the Profession.—Striking Cases of Abuse.—The Special Hospitals.—Abuses encouraged by Medical Men.

THE question of hospital abuse has reached an acute stage at Nottingham. This is due to two circumstances. First, the formation of a strong medical union in that town gives rise to the hope that there is now an organisation capable of taking up the matter; and, secondly, because an effort is being made to raise £50,000 for the purpose of building a new wing to the Nottingham General Hospital. The annual report of this institution, which was issued last April, shows that there were during the last year, 2367 in-patients and 11,562 out-patients; but, as Dr. W. B. Ransom in his speech at the annual meeting observed, "it was a source of considerable anxiety that so many cases had been each week kept waiting for admission. Some weeks there were as many as seventy cases upon the books waiting till room was found for them. The consequent extension of disease and the aggravation of the symptoms had been in many cases distressing to witness." Under such circumstances it is but natural that strenuous efforts should be made to increase the size of the hospital. Hence the proposal arose to build a new wing as a permanent Jubilee memorial, and appeals were published asking for subscriptions to the amount of £50,000. But at the same time a considerable number of practitioners in Nottingham had been murmuring against the prevalence of hospital abuse, and this appeal to augment the scope of the General Hospital increased their irritation. Letters were written to the local papers calling attention to the gross abuse of the hospitals. One of the practitioners in the town refused to join the Nottingham Medical Union till this question of hospital abuse was actively taken in hand by that organisation. During the last few months this feeling has become more and more acute, and the Nottingham Medical Union has been severely criticised by several medical men because it had not dealt with hospital abuse at an earlier period of its existence. But the Nottingham Medical Union was not inactive, although its committee was in a difficult position; for, while anxious to prevent hospital abuse, it was equally anxious not to check the flow of subscriptions for the building of a new wing to the Nottingham General Hospital. The necessity of enlarging the hospital is obvious, but, at the same time, this is a good opportunity for pressing forward demands for the abolition of abuse. The members of the Nottingham Medical Union sought to attain the desired end in a quiet manner and by friendly coöperation with the governing authorities of all the medical charities in the town. They, therefore, convoked a general conference, and hoped to remedy existing evils without damaging the effect of the appeal to the public for more subscriptions. While anxious not to make any disturbance, they thought that it was a good occasion to demand reforms before asking for money. The lay authorities, however, failed to enter into the spirit of this movement. At the monthly board meeting of the Nottingham General Hospital, held in May, 1896, the matter was brought forward by the medical staff, but the board declined to make any alteration in its present system. In vain the medical men protested that no inquiry whatever was made as to the financial resources of either the in- or the out-patients. The lay members of the board thought that any such inquiry would greatly offend the subscribers to the hospital, many of whom were workpeople.

Early this spring an attempt was made to hold a private conference with the various hospital boards, members of the Charity Organisation Society, and medical men. The lay members, however, of the hospital boards were indignant. Some of them said they were not going to be dictated to by outside medical men. Thereupon the Nottingham Medical Union sent round a request to all the members of the hospital staffs, who are also members of the Union, to stand by their Union and exercise their influence on the hospital boards so as to break down such opposition. But the lay members of the boards still persisted in their opposition, insisting, among other things, that there were no facts to go upon. This assertion has been eagerly taken up as a challenge. The Nottingham Medical Union has appointed a special or sub-committee to deal exclusively with the question of hospital abuse, and a circular letter has been addressed to every practitioner in the town asking for information as to cases of abuse which have occurred during the last five years. Without necessarily mentioning names, every practitioner is asked to describe all

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; (9) May 8th, 1897, France, United Action and Legislative Action; and (10) May 15th, 1897, Leicester.

Hosted by Google

the cases with which he is personally acquainted of persons who could afford to pay medical fees and yet who have gone to a hospital. As there is a great deal of indignation in the profession with respect to hospital abuse, it is expected that a large mass of evidence will soon be forthcoming. Some such cases have come to my knowledge—for instance, a short time ago a woman who was about to undergo a dangerous operation sent for a solicitor so that she might make a will. She was overheard giving instructions for a legacy of £1800 to one person, and this was only one of the items in her will. Then a well-known manufacturer sent his wife to the hospital. Another woman, after spending some £300 on medical attendance, came all the way from Australia to be operated upon at Nottingham in a hospital where she paid only 10*s.* a week. Another woman came from Scotland, because some friend had praised the skill of a particular Nottingham medical man, and was admitted into hospital and operated upon at the cost of the Nottingham people. A man in receipt of twelve guineas a week came to the Nottingham General Hospital with a recommendation he had obtained from his father, who was a subscriber. Another person, with an income of £1000 a year, came as out-patient for several weeks and was treated for an affection of the throat. A well-dressed woman was asked if she could not afford to have a private medical attendant, and she indignantly replied: "Of course I can pay for a doctor, but I want superior advice." A well-paid commercial traveller also presented himself, and a well-to-do tradesman drove up in his own trap from a neighbouring village. The latter had been under the care of his local doctor, and came up to Nottingham with a recommendation ticket which he had obtained from the Hospital Saturday Fund.

Members of the management boards urge that the workmen who get up this fund would be very indignant if workmen who go to the hospital became the subject of an inquiry conducted by the Charity Organisation Society. In answer to this it is urged that the abuse does not, as a rule, come from the working-classes. The middle-class tradesmen abuse the hospitals, and this is the class of people whose cases the investigators would have to study and report upon. Most of the working men belong to clubs, and it is easier for them to call in their club medical officer, who is generally nearer at hand, than to go to the hospital. Moreover, if they go to their club medical man's surgery they do not have to wait so long as in the out-patient's ward of the hospital. When workmen do go to the hospital they are often very ill or have been ill for a long time and have been treated by their club medical man and seek for a second opinion. There can be no objection, as a rule, to such applicants. Nevertheless, there is some abuse by working men. No inconsiderable number of chronic or trivial cases present themselves. Nervous debility and depression which cannot be shaken off prevails very extensively in the Nottingham district. As a class colliers seem especially susceptible to this complaint, and sometimes strong, powerful-looking men collapse and burst into tears as soon as they are admitted into the presence of the medical man. Hysteria in males, flatulence, palpitations, and nervous dyspepsia are all very prevalent and help to block up the out-patient's department. Then it is becoming the regular practice for all classes, however rich, to go to the hospital to have fractures set. Even the lay members of the hospital board have declared that they would themselves go to the hospital in such a case.

Needless to say that at Nottingham, as in so many other places, there is not only the question of the abuse of hospitals by the patients, but there is the abuse of hospitals by medical practitioners. In other places than Nottingham I have found that the origin of hospitals which now justly enjoy a high reputation would not bear investigation. In Nottingham there are several special hospitals. Accusations are made that some of these special hospitals are utilised as recruiting-grounds for the securing of private patients. Then there was an advertising hospital. Advice was offered free, but the patients were made to pay a good price for the medicines that were sold to them.

With regard to the special hospitals, the excuse given for their existence is that formerly men who were anxious to work out special departments met with no sort of help or encouragement at the Nottingham General Hospital A practitioner, finding that he had no chance of becoming a member of the medical staff of the Nottingham General Hospital, started a special hospital for the diseases of women. The subscriptions did not suffice to support this hospital, so the in-patients were called upon to pay 10*s.* a week, which was less than half the average cost of their maintenance, but with the aid of the subscriptions this enabled the institution to live. In the course of time, however, two out of the three surgeons on the staff of this hospital disagreed with the committee, and not only withdrew but established a rival hospital for women. Thus to-day there are two hospitals for women—one known as the Nottingham Hospital for Women and the other as the Samaritan Hospital for Women. This certainly seems a waste of forces, particularly as there is also a large amount of gynæcological work done at the Nottingham General Hospital. Both the hospitals for women are obliged to take money from their patients—a registration fee of 1*s.* for out-patients and 10*s.* a week for in-patients. These payments are defended on the ground that there are a great number of women in Nottingham who earn fairly good wages and can afford to pay a small sum. Then, again, the wife of a man earning about £3 a week cannot pay ten or fifteen guineas for an operation, but can contribute 10*s.* a week towards her own maintenance while she is in the hospital. Perhaps such a person might prefer making a payment to going to the general hospital and thus becoming the recipient of an absolute charity. There are also a considerable number of women in Nottingham with incomes of from £30 to £40 a year, and they must inevitably become hospital patients when seriously ill. At the Nottingham Hospital for Women there is no wage limit, and as the hospital was not founded for the very poor it would be difficult to establish such a restriction. Most of the patients come from the town and the immediate neighbourhood. They can easily be recognised by their appearance. The greater part of the in-patients are sent by medical men, and if they are not suitable cases for hospital treatment it is the fault of the medical men who have given them recommendations. But the medical staff of the Nottingham Hospital for Women have the right to refuse patients; yet one of the members of the staff assured me that they did not refuse more than two or three applicants in the course of the year. The fact, however, that surgeons who were at the hospital have now some of their old hospital patients as private patients suggests that there is some abuse, and therefore that a greater number of applicants should be rejected.

Speaking to a surgeon on the staff of the Samaritan Hospital for Women, he expressed his fear that hospital abuse would continue to prevail because the members of the medical profession were not unanimous. There would always be some hospital medical officers who would resist attempts at reform rather than see the number of their out-patients diminished. There were men always willing to give to the hospitals their time and their money so as to build up a reputation for themselves. This was the best, perhaps the only, chance a medical man had of spreading his name; and the better the class of the hospital patients the more remunerative this publicity was likely to prove. Medical men would willingly pay for the privilege of working gratuitously for a hospital, and the more their hospitals were abused by rich people going there the better would the medical man's chance be of getting good private patients. The lay members of the hospital boards lend themselves to this and do not seek to check those members of the medical staff who encourage abuse. The hospital boards and the public generally commit a fundamental error in looking at the quantity rather than at the quality of the work done at hospitals. There should be a central hospital board that would act as an impartial and disinterested check on all these tendencies. This central board should also distribute the general funds where they were most wanted. Then to prevent underselling and the starting of numerous special and rival hospitals, a better chance should be given to new men by constantly changing the honorary staffs. Members of the visiting staff should not be kept on for ever, but compelled to retire after a reasonable lapse of time, so as to make room for younger men. The younger men who have something in them cannot for ever sit with folded arms. When they find they have no chance of gaining admission to the existing hospitals they start hospitals of their own. This difficulty might also be met by the appointment of junior visiting physicians and surgeons. At the Samaritan Hospital for Women there seems to be no attempt to prevent abuse; in any case there is no system whatsoever of inquiry. What is more, it is very frankly stated that no attempt will be made to establish such a system unless it be uniformly applied at all the other hospitals. If all the hospitals would refer doubtful cases to inspectors who would

Hosted by Google

be in the joint employ of all the hospitals, then the Samaritan Hospital for Women would join in such a uniform attempt to deal with abuse. In the meanwhile there is abuse, though many apparent cases of abuse would prove on inquiry to be due to a long drain on the resources of the patients in question. Others who could pay went because they believed in the superior skill of the hospital staff. Thus, a woman went recently to the Samaritan Hospital for Women who was suffering from gall-stone and her husband expressed his readiness to pay a £30 fee. Another patient, who had paid four guineas in consultation fees, wanted to gain admission to the hospital, and would have done so had she not been warned in time. This patient was, therefore, treated in her own home and paid forty guineas in fees. At the same time her niece did contrive to get into the hospital. An operation, abdominal section, was performed upon her gratuitously, though she was just as able to pay as her aunt. The wife of a leading tradesman was in the hospital at the time of my visit. A well-known public man, whose two daughters also earn considerable incomes, sent his wife to the hospital, and, in the same ward in a bed opposite, another patient openly boasted that she had plenty of money and need not work for her living

The only semblance of an organised effort to prevent abuse is at the Nottingham Free Hospital for Sick Children; the board subscribes, in the ordinary way, to the Charity Organization Society. On the tables there are printed forms or tickets, which the visiting staff can fill up as they question the patient, and these tickets are sent to the Charity Organization Society whenever the medical officers imagine they have a case of abuse. But these tickets also serve another purpose; they likewise indicate when the patients are very poor and worthy subjects of charitable relief. The nurse in the out-patients' department is also expected to endeavour to prevent abuse. The ordinary out-patient pays for his medicine at the hospital tariff, but when there is real poverty the medical officer can order the medicine to be given free of charge. The physician attached to the Nottingham Free Hospital for Sick Children on whom I called thought that there was not much abuse. He was, however, of opinion that cases of real clinical interest should be admitted, whatever might be the financial position of the patient.

At Nottingham, as elsewhere, the difficulty arising from enrolling working men as subscribers to the hospital funds has arisen, though it has not yet reached an acute stage. Last year's receipts for the Nottingham General Hospital amounted to £15,884, but from this must be deducted £4853 legacies and cash in hand. Then there were £1448 income from investments and other large sums from entertainments, donations, and more recent legacies. The expenditure was £9448 and this gives us a better idea of what the normal income should be. Now, out of the £10,000 or so wanted for the working expenses, we find that the annual subscriptions yielded £2909, and the Hospital Saturday and Sunday collections £3571. Of this latter sum £2362 are given by the working classes. Collections in workshops, warehouses, mines, &c., were commenced in 1874 and produced during that year £549. It took about ten years to double this amount; now it has increased more than fourfold and is nearly equal to the annual subscription obtained from the other classes of the community. One day the workmen will claim the same voting power in proportion to the amount they subscribe as that actually enjoyed by the other sections of the community; and then at Nottingham, as in so many other places, the workmen will be masters of the situation. Of course, many of the workmen who subscribe 1*d.* a week to the hospital think they have the right to be treated there when ill. One large employer boasted that all his workpeople gave 1*d.* per week and were therefore taking advantage of the hospital, though several among them earned as much as £3 a week. It will be seen, therefore, that though this question of the control of the hospital by the workmen has not yet reached an acute stage at Nottingham, there is all the material necessary for the development of grave complications and difficulties.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday.

STRENUOUS efforts have been made this year to raise the amount of the Hospital Saturday collection to £20,000 in commemoration of the Queen's Diamond Jubilee and the twenty-fifth year of the collection. On May 25th a large meeting was held in the town hall, mainly composed of delegates from the contributing manufactories, former patients in the homes, and subscribers to the fund. The proceedings were enthusiastic, the following resolution being carried by acclamation: "That this meeting pledges itself to use its utmost endeavours to raise the sum of £20,000 for the present Hospital Saturday collection in order that the fund may acquire the freehold of a suitable property as a permanent convalescent home for the women subscribers to the fund. The collection took place on Saturday, May 29th. Up to the present time the amount received has been £15,396 7*s.* 4*d.*, as against £13,777 2*s.* on the same day last year. This leaves still a large deficiency in the required sum, the realisation of which appears somewhat doubtful.

Medical Benevolent Society.

The annual meeting of this society was held recently The seventy-fifth report read by the hon. secretary, Mr. Haslam, stated that the invested funds now amounted to £12,291 19*s.* 5*d.*, and there was a balance at the bank of £31 17*s.* 6*d.* The sixteen annuitants on the books last year were still in receipt of the society's assistance, and none had been added. The annual value of the grants varied from £20 to £40. A donation of £3 was also given to each annuitant at Christmas. The total number of benefit members of the society was 370, twenty-seven having been added during the year. The society had received a welcome addition of two legacies, one of £250 from the late Dr. Sharples, and another of £2000 from the late Mrs. Brumell. Various votes of thanks were passed, and about two dozen of the members dined together after the meeting.

Birmingham and Midland Hospital for Women.

The annual meeting of the governors of this institution was held on May 27th, under the presidency of the Countess of Dudley. The report stated that the number of new cases treated at the out-patient department for the year was 3110, an increase of 185 on the previous year. The total number of new and old cases was 18,046. 345 patients were admitted into the hospital, a decrease of 14, and the total number of operations was 333, a decrease of 22 on the previous year. The number of operations involving abdominal section was 200; 11 patients had died, giving a death-rate of 5 5 per cent. That was a lower death-rate than in the preceding year. The profits on the charity ball held in January added £1300 to the funds. The ordinary receipts amounted to £2366, and the expenditure to £2619 odd. Some special donations had increased the receipts, so that there was a favourable balance of £142 13*s.* The various officers were elected and votes of thanks passed.

Birmingham Asylums.

The committee of visitors, in their report to the city council, show that the number of patients in the asylums on April 1st, 1896, was 1354, and that there were admitted to March 31st, 1897, 402, making a total of 1756. During the same period 167 were discharged cured, 20 relieved, 21 not improved, and 127 died. The health had been good, and the management of the various departments was generally satisfactory. Owing to the progressive increase in the number of patients the board of guardians have expressed regret that they find themselves absolutely unable to relieve the asylums of a considerable number of feeble and harmless patients, who, in the opinion of the medical officers, might be well cared for in a workhouse infirmary.

June 1st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Dr. Hope's Report on Tuberculosis as affecting the Milk-supply of Liverpool.

"THE Report of the Medical Officer of Health on Tuberculosis as affecting the Milk-supply of the City," ordered to be printed by the Health Committee, deals with many subjects of importance to the community. Dr. Hope points out that the erection in years gone by in Liverpool and other great cities of what is known as "insanitary property" constituted an experiment upon a gigantic scale upon man, and has conclusively proved the influence of bad surroundings in the propagation of tuberculosis. The effect of improved

Hosted by Google

sanitation upon tuberculous diseases is shown by the marked diminution of the death-rate from that cause which has taken place in the last thirty years, the death-rate per 100,000 of the population at all ages from all forms of tuberculosis having fallen from 430·8 in 1866 to 292·5 in 1896. Similarly the death-rate per 100,000 of the population above five years of age from phthisis fell from 362·8 in 1866 to 233·1 in 1896; whilst the death-rate per 100,000 of the population below five years from tabes mesenterica, hydrocephalus, and "scrofula," which in 1866 reached 637·1, fell to 496·9 in 1896. Dr. Hope goes on to point out in the report that no domesticated animal is more closely or more continuously confined than the milch cow, nor do the conditions of confinement of any other animal approximate so closely to those of the insanitary human dwellings in which tuberculosis becomes so rife. Cow-houses, shippons, or byres are found, more especially in country districts, in which dirt, darkness, and vitiated atmosphere are constant; under such conditions tuberculous diseases necessarily result. An infected cow may yield a milk in which the tubercle bacillus is present, and it is not improbable that the presence of a cow in an advanced stage of tuberculosis in a bad shippon may lead to indirect contamination of milk in pails, &c., by means of dried infected excretions blown about with dust. Such milk, if taken in a raw state by a susceptible person, may infect that person, and it is to this particular source or means of infection, which has been the subject of much care and attention, that Dr. Hope's report relates. Dr. Hope shows that during the past few years special efforts have been made to improve the condition of the premises in which cows are kept. At the present time no premises are licensed, and no premises will in future be licensed until their sanitary condition fulfils in every detail the requirements of the regulations dated Jan. 6th, 1897. Dr. Hope further deals with the inspection of shippons, dairies, and the analysis of milk (of which about 700 samples are taken annually for analysis under the Food and Drugs Act). The investigations of Professor Boyce, Professor Delépine, Professor D. J. Hamilton, and Dr. Woodhead in search of the tubercle bacillus in the Liverpool milk-supply, which are included in the report, reveal a very serious state of things. They found, as was stated in the columns of THE LANCET last week, that 2·8 per cent. of the samples of milk taken from *city* shippons and examined by them contained the tubercle bacillus, which shows the necessity for a rigorous application of the by-laws. Important as this percentage undoubtedly is, it sinks into insignificance beside the large proportion of milk infected with tubercle which was sent in from the country, which was no less than 29·1 per cent. This large percentage may not be a matter of astonishment to those who are familiar with the condition of many country shippons, but it is a fact which demands the attention of those who are responsible for the administration of those shippons. The tubercle bacillus can be destroyed by boiling for a few seconds, and it is well that this course should be adopted, since milk, as Nature intended it, differs in important particulars from the milk of commerce. Additional powers are required to prevent the erection of town shippons without adequate yard space and without adequate open spaces around them. More direct powers are required to enable the compulsory removal of diseased animals from shippons. Measures are called for to prevent the importation into cities of the diseased products of insanitary country shippons. There is no doubt that much good will result from the report, which has been compiled with great care, and reflects credit on Dr. Hope for the manner in which he has drawn attention to this most important subject.

Hospital Saturday Street Collection.

The anuual street collection in aid of the Hospital Saturday Fund was made on the 22nd ult. in brilliant, summer-like weather. The work of collecting the contributions was carried out by a body of 600 lady volunteers, who were ubiquitous in their appeals for the cause of charity. It is pleasing to be able to record that the collection exceeded that of last year (which realised £507 5*s.* 1*d.*) by nearly £200 The total amount contributed to the Hospital Saturday Fund since its foundation in 1874 has been £73,303.

Presentation to Dr. James Barr.

The residents and nursing staff of the Liverpool Northern Hospital have presented Dr. James Barr, on his retirement from the honorary physiciancy (on appointment to the Royal Infirmary), with a handsome silver inkstand as a token of their esteem and regard. Dr. Barr was very popular at the Northern Hospital, his genial character and high professional attainments gaining for him the respect and affection of both patients and officials, all of whom much regret the severance of his connexion with the hospital.

Death of a Former Chairman of the Royal Infirmary.

Mr. Edward Gibbon, who was chairman of the Liverpool Royal Infirmary from 1851 to 1878, died at his residence at Gateacre, near Liverpool, on the 17th ult., in the eighty-fourth year of his age. His father had also been chairman for a period of twenty-five years, having resigned the office in 1850.

June 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Profession in Glasgow.

AN interesting analysis of the numerical increase of the medical profession in a rapidly extending urban population is contributed by Dr. John Brown to the May number of the *Glasgow Medical Journal*. The statistics are relative to the area which may be called Greater Glasgow, and the periods selected for comparison are the years 1885 and 1897. The municipal boundaries of Glasgow were extended in 1891, but the area taken is the same for both years, and includes, outside the present municipal boundaries, Pollokshaws, Kinning-park, Govan, and Partick—that is, from Springburn and Maryhill on the north to Pollokshaws on the south, Parkhead on the east, and Whiteinch on the west. The corrected local list for Glasgow and these suburbs, given by the Medical Directory for 1885, showed a total of 432 qualified persons, of whom 107 were not in practice, leaving a balance of 325, being all those who did medical work in the specified area, whether general, special, or consultant, including also those who held salaried appointments, but not including the resident assistants in the Royal and Western Infirmaries. Dealing with the year 1897 in the same way the total is 685, of whom 191 are not in practice, leaving a balance of 494 who do the medical work of Greater Glasgow. Thus in the course of twelve years there has been an increase of 169 practitioners actually in practice and 84 not in practice—i.e., a total increase of 253. Simultaneously the population has increased from 718,000 in 1885 to 853,000 in 1897, so that the average population to every practitioner was 2209 in 1885 and 1726 in 1897.

Glasgow Medico-Chirurgical Society.

The following office-bearers have been elected for 1897-98: President: Dr. George S. Middleton. Section of Medicine: Vice-president, Dr. Alexander Napier; Councillors, Dr. Maitland Ramsay and Dr. John Love; Secretary, Dr. Hinshelwood. Section of Surgery: Vice-president, Dr. Newman; Councillor, Dr. John Barlow; Secretary, Dr. J. H. Nicoll. Section of Pathology: Vice-president, Dr. Walker Downie; Councillors, Dr. Rutherford and Dr. W. K. Hunter; Secretary, Dr. R. M. Buchanan. Section of Obstetrics: Vice-president, Dr. George Halket; Councillors, Dr. Edgar and Dr. J. M. Munro Kerr; Secretary, Dr. Balfour Marshall. Treasurer, Mr. Henry E. Clark; General Secretary, Dr. C. O. Hawthorne.

Medical Appointment.

Professor McCall Anderson, M.D., of Glasgow University, has been appointed Examiner in Medicine and Pathology for candidates seeking admission to the Medical Services of the British and Indian armies.

Hospital Extension, Huntly, Aberdeenshire.

Scott's Hospital, Huntly, is to be enlarged by the addition of two wings. In the central portion there will be a new storey with a handsome tower. These additions will about double the accommodation, giving twenty-two new bedrooms and several additional sitting-rooms. Under the will of the late Mr. Morison, of Bognie, £70,000 fell to the trustees to be used on the same lines as the Scott funds, and authority was given to expend not more than £5000 of the principal on extension of the buildings.

Working-class House Accommodation in Aberdeen.

On May 28th (Whit-Sunday removal term) about seventy-five families (numbering 350 individuals) of the poorer classes in Aberdeen suddenly found themselves homeless, having been unable to get dwellings at rents within their

Hosted by Google

means, and their bedding and other furniture lay on the streets exposed to a drizzling rain. The scarcity of available low-rental houses is largely owing to the action of the authorities in condemning habitations in the slums on sanitary grounds and demolishing buildings for street improvements without providing new accommodation. The police took compassion on the homeless people, and by hook or by crook procured quarters of some kind within twenty-four hours for fifty of the families, but most of the rest had to be accommodated for several days with their furniture in the central police office. One of the local papers has offered a prize for the best suggestion (and design) as a remedy for this state of matters.

Aberdeen Company, Volunteer Medical Staff Corps.

This corps (to the number of about 120) went into camp on Thursday, June 3rd, at Cluny Castle, Monymusk, Aberdeenshire, the commanding officer being Surgeon-Captain Booth. The camp will break up on Monday, June 7th, and the men will return to the city by rail. The corps is above the authorised strength, and was never in a more efficient state.

May 29th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Academy of Medicine in Ireland.

THE general secretary of the Academy of Medicine, at the request of the secretary of the Anatomical Society of Great Britain and Ireland, has issued a circular letter inviting the Fellows and Members to attend the several meetings and demonstrations which will be held by the society in the Anatomical School of Trinity College on Thursday and Friday, June 10th and 11th. A tour to Killarney has been arranged to take place on Saturday, June 12th, the excursion leaving at 9.15 A.M., and returning on the following Monday or Tuesday. Full particulars can be ascertained from Dr. W. S. Haughton, 113, Lower Baggot-street, Dublin. Professor Wilhelm His, of Leipzig, will deliver an address on the Development of the Brain and Nerves in Connexion with It to the Fellows and Members of the Royal Academy of Medicine in the theatre of the Royal Dublin Society, on Friday, June 11th, at 4 P.M.

The Royal College of Surgeons in Ireland.

Great interest is felt just now in the election of Vice-President of the College of Surgeons for the year 1898. Three candidates are thus early in the field: Dr. Charles Ball, Dr. Lambert Ormsby, and Mr. T. Myles.

The Apothecaries' Hall of Ireland.

Mr. Arthur Chance, surgeon to the Mater Misericordiæ Hospital, Dublin, and Mr. H. A. Thomson, assistant surgeon to the Royal Infirmary, Edinburgh, have been appointed by the General Medical Council examiners in surgery for the Apothecaries' Hall.

The Samaritan Hospital.

On Friday, May 28th, in the presence of a large and representative assembly, the new wing which has recently been added to this institution was opened by Miss Benn, the sister of the late Mr. Edward Benn, who was the founder of the hospital, and by Mrs. Forster Green, whose husband has built the new wing. In the new buildings added to the hospital there are two wards, each of which will accommodate four or, on an emergency, five beds, and each of which is complete with bathrooms, lavatories, &c., while on the ground-floor of this wing there are two bedrooms for nurses and a dining- and also a sitting-room for their use. A new dispensary has been formed, the whole of the old part of the hospital premises has been renovated, and one of the old apartments is being transformed into an operation ward, which will be fitted with the most scientific appliances.

June 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Mercury and Non-syphilitic Lesions.

DR. FOURNIER has communicated to the Society of Dermatology an interesting case of rapid and radical cure of certain non-syphilitic cutaneous lesions under mercury. The patient bore on his arms and hands enormous ulcers of several years' duration, the nature of which was never in doubt. They were tuberculous and had resisted all treatment. No history of syphilis was forthcoming. By accident he gave himself an hypodermic injection containing ten centigrammes of calomel. After an acute attack of stomatitis the ulcers presented a decidedly healthier surface and the treatment was continued. In three weeks the tuberculous patches of two years' duration were replaced by healthy skin. Dr. Fournier concluded from the success of this case that specific treatment in doubtful cases has not the value attributed to it as proof of the existence or absence of syphilis, and he regrets now that he has often attributed to syphilis destructive lesions of the face, which were probably simple lupus, although they improved under mercury. He recalled one case of lupus of the face that had improved markedly under an injection of calomel. In view of this statement in the nature of a confession by one of the chief of French syphilographers, other members of the society plucked up courage to relate analogous cases, the details of which they had hitherto hesitated to publish. M. Auganeur mentioned that he had obtained a cure in a case where tuberculous mischief had lasted for ten years by the energetic exhibition of iodide of potassium. M. Sabourand related to the meeting that the only two cases of human glanders in which he knew a cure to have resulted had been mistaken for syphilis and treated with mercury. The results obtained in psoriasis by Haslung's method and by the employment of iodide of potassium were also alluded to as bearing on the point, the net result of the debate being a rude blow to the classic adage—*Naturam morborum curationes demonstrant.*

The Treatment of Gastritis: Reichmann's Disease.

A lively discussion took place at the Academy of Medicine recently upon this subject, so lively that it verged upon a personal dispute between M. Hayem and M. Albert Robin. On a previous occasion M. Hayem had declared that patients suffering from "gastro-succorrhée," or Reichmann's disease, a condition characterised by the presence of liquid in the fasting stomach, could only expect cure from surgical interference. M. Robin asserted, on the contrary, that medical treatment could not only benefit but actually heal the patient, and quoted a number of observations in which patients of M. Hayem who had been operated upon surgically had been found to suffer from spasm or pyloric contracture without lesion, while M. Hayem had asserted that stenosis is always accompanied by lesion. M. Hayem replied that none of the cases cited by M. Robin had suffered from Reichmann's disease, and that, among others, a woman whom he had treated, and to whose case allusion was made, was an hysteric in whom the particular symptom of Reichmann's disease—namely, liquid in the stomach—had never been present. He pointed out the weakness of the position taken up by his opponent in quoting cases against him which had been only alleviated, not cured. M. Robin replied that he was quite aware of the symptoms of Reichmann's disease as described by all the authors. M. Hayem replied that he had only met with the condition twice in a long career, so that it was certainly very rare, and the frequency with which M. Robin had met with it astonished him. M. Debove tried to reconcile the opponents by saying that without either sharing the views of M. Hayem or opposing them he awaited more convincing observations than those which had been furnished.

Reform in the System of Concours.

The methods by which the medical staffs of the Paris hospitals are elected have for a considerable time been subjected to much criticism both by the public and by the candidates themselves. It should be understood that *concours*, as this method is termed, is a public examination divided into two parts. The first of these is a series of written tests in anatomy and pathology, and is of a qualifying nature. Success in it allows the candidate to enter upon a second or clinical part where the examination of patients and the publication of original work count. The chief grievance of the candidates is that they are compelled always to qualify, so that if at the end of *concours* they are not successful they have on each occasion on which they compete to begin at the beginning again. From this it follows that those who aspire to be chosen on the staffs of the hospitals, and who represent the flower of young French medicine, are compelled to pass perhaps ten years of their life in revising the exercises of pure memory demanded of candidates in written

Hosted by Google

examinations upon anatomy and theoretical pathology. Every one agrees that their time would be much better spent in perfecting their clinical knowledge or making original research, and the petition which has emanated from the candidates asking that they shall not be required to qualify more than twice has obtained support from several of the examiners and teachers. It is considered that the profession will gain, inasmuch as the selected men will be free from the evidences of intellectual fatigue and will not have lost heart for original work by repeated plodding over elementary matters. Nor is this the only objection that has been taken to *concours*. One of the members of the last jury, M. Variot, has had the courage to publicly assert what has been very generally hinted—that private influence grows daily more influential in dictating the choice of candidates. M. Variot stated, with unkind frankness, that three recent candidates had been already pronounced by public opinion elected before they had undergone any test, and that by the simple process of calculating the chances that they would have among their teachers or personal friends on the jury. Speculation turned out completely right, and the three candidates who were then nominated before the tests came out triumphantly at the top of the poll. A somewhat similar occurrence amused the public much some two years ago, when, on the opening day of *concours*, the names of the jury being known, a political paper published a note that had evidently been inspired by a humorous candidate, but which the journal thought to be serious information, in which it was gravely announced that *concours* was over and had resulted in the choice of three persons whose names followed.

May 31st.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Bacteria in Parotitis.

AT a recent meeting of the Verein für Innere Medicin Dr. Michaelis, assistant to Professor v. Leyden, read a paper on bacteria discovered by him and Dr. Bein in cases of mumps or epidemic parotitis. Professor v. Leyden had drawn the attention of his assistants to characteristic diplococci present in the sputum of a child suffering from this complaint, and Dr. Michaelis accordingly made a bacteriological examination of seven other cases. He succeeded in proving the presence of these diplococci in every instance not only in the secretion of Steno's duct, but also twice in the pus of the suppurated gland and twice in the blood taken from the veins of the patients. He described the diplococci as being 1 μ in length, and in form very like gonococci, only somewhat smaller. They were, as a rule, found in the interior of the cells, a cell containing from eight to ten of them; but some were arranged in long rows outside the cells, so that they might be regarded as streptococci. Another feature was that they were unusually motile. They could be stained with the usual aniline colours, especially with methylene-blue and also after Gram's method. They were cultivated on the usual media, and grew slowly. On agar they formed small, limpid points, not confluent, very like dewdrops. When they were cultivated in peptone broth a white, granular sediment appeared, the broth itself remaining clear. Their growth depended upon the degree of alkalinity of the medium. Dr. Michaelis also succeeded in cultivating them in ascitic fluid and in milk, which became coagulated within forty-eight hours. Injections of the cultures in animals gave negative results, one case excepted, where a white mouse died within thirty-six hours; the injections were made in the parotid glands of mice, rabbits, cats, and dogs, and in the testicles of guinea-pigs. In healthy persons the above-described diplococci were never found. Dr. Michaelis remarked that Pasteur long ago described bacteria present in the blood of patients suffering from mumps, and that Capitan, Charrin, and Olivier observed cocci and bacteria in the blood and in the urine. Boisset discovered in the blood micro-organisms which were partly diplococci and partly streptococci. The bacteriological researches of Laveran and Mecray gave results similar to those of Dr. Michaelis, they found diplococci in the blood and in the secretion of the gland, and were able to cultivate them.

Kryofin: a New Antipyretic.

Professor Eichhorst, of Zürich, has recently described in the *Deutsche Medicinische Wochenschrift* a new antipyretic to which the name of kryofin has been given. He considers that as a rule the administration of antipyretic remedies is quite unnecessary, and in his clinic such drugs are therefore hardly ever used. An exception has, however, been made in the case of kryofin principally for the purpose of ascertaining its physiological action. Kryofin belongs to a series of chemical compounds which have been investigated by Dr. Bischler, one of the chemists of Zürich University. Kryofin, like phenacetin, is a phenetidin derivate, and is prepared by acting on para-phenetidin with methyl-glycol acid at a temperature from 120° to 130° C. It forms white crystals which are inodorous and tasteless, so that they can be easily swallowed in the form of powder. It is soluble in 52 parts of hot water and in 600 parts of cold water. In a concentrated solution it tastes bitter and acrid. The dose of kryofin was stated to be half a gramme (7½ grs.), the effect being like that of one gramme (15 grs.) of phenacetin. In cases where kryofin failed the other antipyretic compounds—phenacetin, lactophenin, and antipyrin were equally unsuccessful. Professor Eichhorst gave a detailed account of five cases in which kryofin had proved beneficial. Two of the patients suffered from enteric fever, one from pneumonia, one from puerperal fever, one from acute Bright's disease following scarlet fever, and one from erysipelas of the face. In every instance the administration of kryofin brought down the temperature to the normal in from five to six hours, and the pulse simultaneously fell from 120 per minute to 80 or 90. The remedy also proved useful in cases of pulmonary tuberculosis, diphtheria, tubercular meningitis and endocarditis. There was sometimes profuse perspiration while the temperature was in course of falling. The blood-pressure in the arteries was measured with Dudgeon's sphygmograph and Basch's sphygmomanometer, and in the radial artery it showed an increase to the amount of from ten to twenty-five millimetres of mercury. Kryofin also proved to be a good antineuralgic remedy; in several cases of recent sciatica its effect was very remarkable. In one instance of alcoholic polyneuritis where salicylate of soda, phenacetin, antipyrin, and exalgin had been given without any effect, three half-gramme doses of kryofin daily caused the severe pains to disappear. In acute and chronic rheumatic arthritis it appeared to be less efficacious.

Over-exertion in Cycle-races.

Dr. Albu recently made an interesting communication to the Berlin Medical Society on certain effects produced on the heart and other internal organs by over-exertion in cycle-races. His conclusions were based on the condition of twelve professional cyclists whom he had examined both before and after races lasting from five to thirty minutes. The strain thrown on the heart was shown by well-marked dyspnœa, and by the strong pulsation of the heart and arteries, but the most remarkable fact was an acute dilatation of the heart, especially of the left ventricle. This dilatation is of course temporary, disappearing when rest has been taken and returning on the occasion of the next race. When over-exertion is frequent this dilatation may become permanent, and in a heart that was previously weak an irreparable injury may occur. Another symptom was the presence of albumin and casts in the urine, caused by the kidneys being irritated by the effort of cycling. Dr. Albu believes that cycling in moderation is for most persons a very salutary form of exercise, and he explained that the dangers he had described were only incurred by professional riders and competitors at matches.

May 29th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

X Rays in Legal Cases.

THE Roentgen x rays are beginning to be received in courts of law as a reliable method of obtaining evidence in doubtful cases. A man has brought a suit against a railroad for $10,000 on account of the failure of the physician to secure satisfactory results in a fracture of the wrist. A skiagraph has been taken of the injured joint which the court will admit as satisfactory evidence of the present condition and future usefulness of the limb. In another case of a suit for $20,000, on account of alleged false diagnosis of an injury that led to treatment of contusion instead of fracture,

Hosted by Google

the x rays were recognised in court as disclosing the true nature of the injury. In another State the x rays were admitted in evidence by the court in a case of alleged malpractice in setting a fractured leg.

Street Cleaning by Direct Labour.

The two cleanest cities on the continent to-day are Toronto and New York, and they are both cleaned by direct labour New York not only employs and thus directs all its street-cleaning forces, but it has an organised department, with an adequate and properly adjusted equipment of horses, carts, brooms, stables, and stations, and it pays its men $2.00 a day and upward for eight hours' work. It is by the method of direct labour under model conditions of employment that this first worthy result of the kind in a large American city has been achieved. Toronto, the other of these two exemplary cities, has gone even further than New York in eliminating the contractor. In this interesting Canadian town, with its 190,000 people, Street Commissioner Jones has during the last seven years entirely revolutionised the care of the streets of the city. He has not only organised the execution of this work under a distinct department, but out of the margin thus saved from the annual appropriations for caring for the streets he has actually built and equipped a modest but complete set of workshops, where the entire construction and repair work of the department is executed. A considerable element of this saving of labour has been due to the automatic loading machines, invented in these shops, which elevate the litter directly from the street into a dump-cart as rapidly as horses can walk.

Public Health in North Carolina.

The State Board of Health of North Carolina held a meeting on March 12th, for the purpose of trying to enlist the coöperation of medical associations and other State Boards in urging upon the National Government the necessity of properly draining the swamps and rivers, and thus removing one of the most fearful causes of death—malarial fever. Another matter discussed by the Board was as to the best means of checking the ravages of tuberculosis among the negroes. It was decided to issue a circular to all coloured school teachers explaining this fact, and showing that the most fruitful cause of the spread of this disease was the habit of expectoration by tuberculous patients on the floors of school buildings and elsewhere.

May 17th.

THE MIDDLESEX HOSPITAL.—H.R.H. the Duke of Cambridge presided on May 27th at a special quarterly general court of governors, at which it was resolved to present an address to Her Gracious Majesty the Queen, patron of the hospital, on the occasion of the sixtieth anniversary of her reign. Sir Ralph Thompson read the terms of the address, in which reference was made to the munificent gifts graciously bestowed upon this charity from time to time by Her Majesty, and also to the fact of her having acted as the patron of the hospital throughout the long period of her beneficent reign. The address continued: "Your Majesty's reign will be conspicuous, not only for the great advance in the science of medicine and for the establishment of a body of highly-trained nurses, but for the endeavours made, under the stimulus and encouragement of your Majesty's bright example, by members of the Royal Family to alleviate the sufferings of the sick, which has now culminated in the noble and generous effort by H.R.H. the Prince of Wales to raise such a lasting fund for the benefit of the hospitals of London as will render the sixtieth year of Your Majesty's reign specially marked in their annals." His Royal Highness, in the course of some remarks, referred to the progress of medical and surgical science during recent years, and to the great interest which Her Majesty and the other members of the Royal Family had always manifested in the welfare of the various hospitals. He was glad that the old hospitals were coming to the front on the present occasion, because there were a great many new hospitals now which were anxious to gain public notoriety, and while they received large subscriptions the old institutions were apt to be left in the shade. This was not due to any want of respect for the old hospitals, or because they were not performing their duties properly. The old hospitals were just as good as the new ones, although their premises could not be so good as those which were erected with all the modern requirements.—A vote of thanks was accorded to His Royal Highness for presiding.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE Summer Session of the General Medical Council came to an end on Monday last with a vote of thanks to the veteran President. It is not too much to say that courage, energy, and devotion to duty have seldom been more extraordinarily displayed in a public capacity than they have been by Sir Richard Quain during the sitting of the Council which has just concluded.

The penal business of the General Medical Council at its late meeting was not very heavy. One case was that of a practitioner of eighty years of age for "covering" an unqualified assistant. The offence was held to be proved; but the practitioner was not quick in the apprehension of his fault. He had consulted a solicitor, who had told him that "anybody might practise medicine." The Council mercifully gave him time to consider his position, while he on his side promised to see that no patients were treated by an unqualified assistant. In two cases the Council proceeded to order the removal of the practitioner's name from the Register.

The position of the General Medical Council towards the Midwives Bill is not easy to comprehend. On Wednesday, May 26th, on a motion proposed by Dr. McVail, and seconded by Dr. Thorne Thorne, the Council inquired whether the Privy Council still desired that the Midwives Bill should be considered during the present Session. The Privy Council replied promptly that it would "be desirable to hear the opinion of the General Medical Council during the present Session." It was accordingly moved that the Council should do as the Privy Council desired, but the motion was lost, and an amendment was carried that the Bill in question should be referred to a committee for consideration and report next November. We agree with Dr. Pettigrew, who said that in his opinion the Council were bound after having approached the Privy Council to act at once. The second reading is now fixed for Wednesday, June 30th, or four months before the Council propose to deliberate and report upon it.

Mr. Thomson did well to direct the attention of the Council to the range of surgical questions put on the examination of dentists by the Royal College of Surgeons of England, as if it were intended that the examinee should take medical charge of the whole head and body. Mr. Bryant promised to bring the matter under the notice of his College.

There was an interesting debate on Saturday, May 29th, on the disciplinary power of the Universities. It seems to us, as it seems apparently to the Privy Council, quite clear that the Universities ought to be able and willing to deprive University graduates of their status. What Professor Allbutt meant by writing on behalf of the Special Board of Medicine of Cambridge University that "the guilds of the profession ..... are the proper bodies to keep up a continuous standard in the ethics of the profession" we do not quite know; but the Board has certainly forgotten to take into consideration the possible case of an ill-behaving medical graduate of Cambridge who does not happen to be a *diplomé* of any guild.

The Council, in accepting Mr. Miller's resignation, has, we are glad to see, awarded him a gratuity of £1000. He did very valuable work, and his sudden breakdown has been a

Hosted by Google

subject of sincere commiseration. The vacancy has been filled by the appointment, subject to annual election, of Mr. H. E. Allen, acting registrar, who has served the Council for eighteen years.

The doom of the unqualified assistant has been practically pronounced this session. The somewhat vague regulations made by the Council recently have not abated the scandals arising out of the improper use of unqualified help, and the next move will be to permit only genuine medical students to sell their services, and then only in such a way as to preclude covering. That such regulations will bear hardly upon a diminishing body of men is true but inevitable.

The finances of the Council are always a matter of interest, and must become more so if Dr. Rentoul gets his way and sees the Council become a great spending department. Last year the income of the General and Branch Councils was £1526 18*s.* 10*d.* less than the expenditure. It is noticeable that the receipts from registration fees were less in Scotland and Ireland than in the previous year, though they were more in England. The chief explanation of increased expenditure in the last four years given by the treasurer is the cost of the inspections of examinations and of the preparation of the Pharmacopœia.

The Council may, on the whole, be congratulated on having got through good work quickly.

THURSDAY, MAY 27TH.

Last week we reported the proceedings of the first two days of the session of the Council, and this week we begin with the third day, when Sir RICHARD QUAIN again presided.

The Case of Rees Thomas Edward Davies.

The Council proceeded with the adjourned consideration of the case of Rees Thomas Edward Davies, of New Tredegar, *vid* Cardiff, who at the session in November was charged: "That he systematically authorised, permitted, and enabled unqualified persons, under cover of his name and qualifications, to administer medical treatment to patients and generally carry on medical practice and perform the duties which can properly be performed only by practitioners recognised by law." On that occasion the Council found the charge had been proved, but postponed the further consideration of the case.

Mr. FARRER, solicitor to the Council, said that Mr. Davies was now in attendance. During the time that had been left to him to amend his ways he had got rid of both the unqualified assistants, whom he was said to have improperly employed, and the complainant, Mr. Francis Ignatius Maunsell, Tir Phil, Cardiff, had written to say that for the last three months or more Mr. Davies had been employing qualified men, so that the object of the censure of the Council had, he might say, been attained.

Mr. DAVIES, in reply to the President, said he had discharged the unqualified men and replaced them by qualified assistants.

Mr. BROWN said he should like, through the President, to ask Mr. Davies whether he could give the Council any information as to what had become of his late unqualified assistants.

The PRESIDENT said that was no affair of the Council.

The Council then deliberated in private on their decision.

The PRESIDENT thereafter intimated to Mr. Davies that the Council had further considered the charge made against him, and did not adjudge him guilty of infamous conduct in a professional respect. He had done wisely in accepting and adopting the suggestion of the Council, and he had had a very fortunate escape. He hoped this would be a lesson to him and his neighbours in the future in regard to the employment in their practice of non-qualified assistants.

Mr. DAVIES asked for the advice of the Council in these circumstances. The men he had were leaving, and though he had advertised for the past month for a qualified man he had not been able to get one.

The PRESIDENT said the Council could not proceed further in the matter.

The Case of Timothy Siddall Jones.

The Registrar was directed to erase from the Register the name of Timothy Siddall Jones, late of Gowerton, Swansea, who in November last at Swansea was convicted of manslaughter and sentenced to penal servitude for life.

The Case of Daniel Costelloe.

On the report and recommendation of the Executive Committee the Council decided to restore the name and qualifications of Daniel Costelloe to the Medical Register. The removal was made on Dec. 5th, 1894, in respect of a charge of covering.

Address to Her Majesty.

Sir WILLIAM TURNER read for the approval of the Council the terms of an address to be presented to Her Majesty the Queen on the occasion of the completion of the sixtieth year of her reign.

They were cordially approved, and it was arranged that, as in 1887, each member of the Council should sign the address. Etiquette prevents the terms being given in this report.

Death Certification.

The PRESIDENT repeated what he said on this subject in his opening address. He added that the statement which had been drawn up for presentation to the President of the Local Government Board mentioned some very important particulars in which death certification might be improved. One recommendation, he said, was that undertakers should be registered and have a sort of licence, and another was that births and marriages should be separated from deaths. He hoped that the deputation would be received by the President very soon.

The Society of Apothecaries of London.

Mr. BRUDENELL CARTER intimated to the Council the retirement by rotation of Mr. Adams Frost from the office of assistant examiner to the Society of Apothecaries of London, and moved the appointment in his stead, for a term of five years, of Mr. Louis Albert Dunn, M.B. and M.S. Lond., F.R.C.S Eng., L.S.A., assistant surgeon to Guy's Hospital.

Mr. BRYANT, in seconding the motion, said that Mr. Dunn was an excellent all-round man, and would see that a proper standard of proficiency was maintained at the examinations.

Dr. MCVAIL said it was a very pleasant thing to find the representative of the Royal College of Surgeons of England so cordially seconding the nomination of the representative of the Society. It would be a much greater pleasure to the Council if the Royal College of Surgeons of England would unite with the Society to form a conjoint board and so relieve this Council of the necessity to appoint assistant examiners.

The motion was agreed to.

British Medical Men Abroad.

Mr. ALLEN, Acting Registrar, read the following letter:—

"6, Via Finanze, Rome, May 22nd, 1897.

"DEAR SIR,—The Under-Secretary of the Italian Parliament has announced that he is about to introduce a project of law for the purpose of modifying Article 23 of the Sanitary Law, which permits foreign doctors practising their profession among foreigners in Italy. The reason assigned for this change is that Italian doctors are not permitted to practise in the other countries of Europe, including the United Kingdom, without possessing the diplomas of the respective countries.

"Now, as you are aware, this is not a fact as far as England is concerned, because foreign practitioners can exercise their profession in the United Kingdom, but under certain restrictions if they are not registered. Besides, under the Medical Act of 1886 the General Medical Council have the power to recognise equivalent qualifications obtained in countries which treat the United Kingdom with reciprocity.

"As this proposed change is of vital importance to all the British medical men practising in Italy, particularly if the law should be made retrospective, a meeting of the British medical men practising in Rome was held on the 10th instant for the purpose of guarding our interests in this relation.

"The meeting unanimously agreed that Mr. Eyre and Dr. Brock should form a deputation, representing all the British and American doctors practising in Italy, to call upon the British and American Ambassadors for the purpose of obtaining their powerful aid; that they should endeavour to obtain an interview with the Minister of the Interior for the purpose of placing the above facts before him; and that they should also act for the other English and American doctors practising in Italy. The meeting also requested me to write to our colleagues in Italy requesting their adhesion to these resolutions.

"We have seen the English Ambassador, and he has kindly promised to do all he can for us. We have applied for an audience with the Minister of the Interior, but have not yet had a reply to our letter. I have heard from nearly all the other British doctors in Italy, and they approve of what we have done.

"It has occurred to me that this is an excellent opportunity for us to endeavour to carry into effect the 'reciprocity clause' of the Medical Act of 1886, and I shall, therefore, feel very grateful if you will kindly

Hosted by Google

tell me what are the necessary steps to be taken for the purpose of obtaining this object, so that I may acquaint my colleagues with them.

"I remain, dear Sir,

"Yours faithfully,

"JOHN J. EYRE."

Sir WILLIAM TURNER said that the subject of this letter was no new question; a very elaborate report prepared three years ago by the President gave the fullest information with regard to it up to the date of the report. He would suggest that copies of this report should be sent to Mr. Eyre so that he might see the exact position of the question and the attitude taken by this Council. He was sorry to say that the countries which were especially the offenders, France and Switzerland, had paid not the least attention to anything the Council had suggested. The letter might also be sent to the Privy Council.

Dr. GLOVER said he would be glad to second Sir William Turner. He thought the matter so urgent that they should communicate directly with the Privy Council, and he hoped they would get from Italy a better answer than they got from France.

The PRESIDENT said it was remarkable to hear this from Italy, because they had held up the country as a noble example of freedom to foreign practitioners. Now, it appeared, Italy was going to follow the bad example of the neighbouring countries, and he thought it most desirable that a representation should be made to the Privy Council, who would communicate with the Foreign Office, and no doubt something might be done in that way.

Dr. HERON WATSON asked whether there was any convention between this country and Italy whereby Italian practitioners could practise here. So far as he knew they could only practise here as any quack could practise.

Mr. BRUDENELL CARTER called attention to Section 12 of the Act of 1886, which said: "On and after the said prescribed day, where a person shows to the satisfaction of the Registrar of the General Council that he holds some recognised foreign medical diploma or diplomas (as hereinafter defined) granted in a foreign country to which this Act applies, and that he is of good character, and that he is by law entitled to practise medicine, surgery, and midwifery in such foreign country, he shall, on application to the said registrar, and on payment of such fee not exceeding £5, as the Council may from time to time determine, be entitled, without examination in the United Kingdom, to be registered as a foreign practitioner in the Medical Register."

Dr. MACALISTER pointed out that before the foreign practitioner could be registered in this way there must be the antecedent order in Council; the Privy Council must be satisfied in this case, for instance, that Italy had granted reciprocity to us.

Mr. MUIR MACKENZIE said that Section 17 of the Act gave power to Her Majesty in Council to define colonies and foreign countries to which Section 12 should apply.

Dr. MACALISTER: And the moment Italy begins we are ready to follow.

Sir WILLIAM TURNER: Quite so; the foreign country must take the initiative.

It was then agreed to furnish Mr. Eyre with six copies of the memorandum and to appoint a committee, consisting of the President, Sir Dyce Duckworth, Dr. Thorne Thorne, and Mr. Carter, to frame and forward to the Privy Council a representation calling attention to the subject of Mr. Eyre's letter and asking that the Secretary of State for Foreign Affairs might be moved to take such action as was possible in regard to it.

Pharmacopœia Committee.

The following report was presented and adopted, viz.:—

The Pharmacopœia Committee report to the Council that the progress of the work of revision of the British Pharmacopœia can be readily estimated from the draft proofs which have been issued to the members of the Council. These comprise the whole of the text of the volume, and the work which remains to be done consists of the preface, the completion of the appendix, and the preparation of the index. It is proposed to place the modifications desired by the colonies in the appendix, and it is also proposed to somewhat alter the arrangement of the index so as to include complete lists of official preparations, and also the doses. In the labour of revision the Committee has received most valuable assistance from all the referees, who have contributed many very useful criticisms and suggestions. From the present condition of the revision it is hoped that it may be possible to place the completed volume before the Council at the next meeting in November. The Committee cannot ensure this result unless all copies of the draft now issued are returned by June 30th, 1897.

The Case of Robert Alexander Douglas Lithgow.

The Council then proceeded with the consideration of the case of Robert Alexander Douglas Lithgow, of 27A, Lowndes-street, Belgrave-square, S.W., registered in England May 5th, 1873, as Lic. Soc. Apoth. Lond. 1871, Lic. 1872, Mem. 1880, R. Coll. Phys. Edin., Lic. R. Coll. Surg. Edin. 1872, M.D. Univ. St. And. 1890, who had been summoned to appear before the Council to answer the following charge on the complaint of the Medical Defence Union:—

"The complaint has relation, firstly, to Dr. Lithgow's alleged association in medical practice with William Maunsell Collins, of 10, Cadogan-place, an unregistered person, whose name was erased from the Medical Register by direction of the Council pursuant to the 29th Section of the Medical Act, 1858, on the ground that he had been convicted of felony, but who still held the qualifications of M.D., Mast. Surg. of the Queen's University of Ireland; secondly, to his alleged association with, and support given to, an unqualified person named Mrs. Maitland King, who purports to carry on, or has carried on, a medical practice at 49A, Park-street, Grosvenor-square, and 31A, Grosvenor-street, Grosvenor-square, or one of those places. With regard to Dr. Lithgow's association with William Maunsell Collins, it is alleged by the complainants that he had acted as cover to him, and by his presence, advice, and assistance, and meeting him in consultation, and certifying deaths for him, had enabled W. M. Collins, notwithstanding the erasure of his name from the Medical Register, to carry on a medical practice as though he was still duly registered. In particular it is alleged that he so acted as cover to W. M. Collins in the particular case referred to in the depositions taken before the Coroner for West Middlesex on July 4th, 1895, a copy of which is before the members of the Council. With regard to his association with Mrs. Maitland King, the complainants allege that she carries on a so-called establishment for private massage and medical electric treatment, at which she professes to administer medical treatment to patients, and carry on a medical practice, and that such establishment is carried on under, or assisted by, Dr. Lithgow's medical supervision.'

Mr. R. W. Turner, instructed by Mr. W. Hempson, solicitor, and Dr. Bateman appeared for the Medical Defence Union, and Sir Frank Lockwood, Q.C., and Mr. Montagu Lush, instructed by Mr. Percival Ray, solicitor, appeared for Dr. Lithgow.

Mr. TURNER said that Dr. Lithgow attended a patient at the request of Dr. Collins from June 10th, 1895, onwards until the death of the person on June 18th; for obvious reasons he was unwilling to introduce the patient's name. At the beginning of this attendance Dr. Collins was confined to his house by indisposition, but on June 14th they visited the patient together and made an examination. Dr. Lithgow admitted that he saw the patient again on June 15th, but he did not point out, as was pointed out elsewhere, that he and Dr. Collins met at the patient's house. On June 18th he was sent for, and on his arrival, the second time that day, he found the patient dead, and he gave a certificate of death, which certificate was found at the coroner's inquest to be incorrect. The statements of the various counsel engaged in the case showed that Dr. Collins was removed from the Register, not for unprofessional conduct, but in consequence of his being convicted at the Old Bailey of felony—viz, of forgery; no sentence, however, was passed upon him, and he was released upon his own recognisances. Mr. Muir Mackenzie further pointed out that when infamous conduct in a professional respect was charged the Council inquired into the facts, but in the case of a felony they simply proceeded upon the certificate of the officer of the court. Mr. Turner then went on to state that Mrs Maitland King was not registered as a medical practitioner in this country. She carried on a massage practice, styled herself "Mrs. Dr. Maitland King," and said that she acquired the degree of "M.D. U.S.A." after five months' study. In the *Provincial Medical Journal* of January, 1894, Dr. Lithgow published himself as consulting physician to Mrs. Maitland King's establishment. A pamphlet which said that Mrs. Maitland King's massage establishment was highly recommended by Dr. Lithgow was also published both before and after this matter was brought to Dr. Lithgow's notice; it was on the subject of corpulence and other ailments of women, and contained a compilation of advertisements.

Sir FRANK LOCKWOOD then opened the defence, saying that Dr. Lithgow was glad to have an opportunity of meeting the charges which had been made against him, and submitted testimonials which he had received from several distinguished men. Dr. Lithgow had long been acquainted with Dr. Collins, and after his misfortune he still remained his friend. Dr. Collins, being indisposed, was not able to visit this patient, and Dr. Lithgow accordingly attended her, as he would have attended any person in society. The account given to him was that the lady had been bicycling and suffered from a chill. After he had attended her for two or three days he and Dr. Collins met, and that which was said to be an operation, but was really an examination, was performed by Dr. Collins. No operation in the ordinary sense was performed, Dr. Lithgow was absolutely unprepared for what was disclosed at the post-mortem examination, and he gave to the best of his ability a certificate of the cause of death. The Council might think that

Hosted by Google

Dr. Lithgow had acted imprudently or even improperly; but he begged them to believe that if he had erred he had done so from want of thought. As regards Dr. Lithgow's association with Mrs. Maitland King, her establishment was not carried on under his supervision, neither had he ever seen a patient along with her; he had only visited people there and examined them to see whether they were fit for her treatment. This conduct the Council might condemn, but was it a justification for driving the man from his profession?

Dr. Lithgow was then examined by Sir Frank Lockwood, cross examined by Mr. Turner, and questioned by several members of the Council, after which it was agreed that the case should be closed and the Council adjourned.

FRIDAY, MAY 28TH.

The Council resumed work to-day, Sir Richard Quain presiding.

The Midwives Bill

Sir WILLIAM TURNER said he wished to interpolate a matter of pressing business. It was within the recollection of the Council that on the first day of the session a motion, moved by Dr. McVail and seconded by Dr. Thorne Thorne, was carried that inquiry be made as to whether the Privy Council still desired that the Midwives Bill should be considered during the present session of the General Medical Council. This morning there had reached them the following letter marked "pressing" from Sir Charles Lennox Peel, viz:—

"Privy Council Office,
"Whitehall, May 28th, 1897.

"SIR,—I have submitted to the Lord President of the Council your letter of the 26th instant, inquiring if the Privy Council still desire, at this period of the Parliamentary session, to have the opinion of the General Medical Council on the Midwives Bill now before Parliament, and I am directed by the Lord President to state, for the information of the Council, that his Grace is of opinion that, as the Bill may be introduced again next session and may then obtain a more favourable position in the ballot, it will be desirable to hear the opinion of the General Medical Council—during the present session—on the Bill for the information of Her Majesty's Government

"I am, Sir, your obedient servant,
"C. L. PEEL.

"The Secretary of the General Medical Council."

The Council would require to acknowledge receipt of this letter, and the next question was whether the Council were still of opinion that this Bill was pressing, that it was likely to be brought forward and carried to an issue during the present session. If it was not likely to be brought forward and carried to an issue during the present session then it could be taken up by this Council next November. If it was likely then it was clear they would have to deal with it now.

Dr. RENTOUL moved that the consideration of the letter be postponed until a later sitting of the present session. He did so because the second reading of the Midwives Bill was fixed for Wednesday, and because there was some difference of opinion in the Council as to whether the Council should deal with it during the present session.

Mr. BROWN, in seconding this motion, said that if the Bill was blocked, as probably it would be on Wednesday, it was not likely to be brought on again during the present session of Parliament. At the same time, having received this important communication from the Privy Council, and it being evident that the Privy Council desired the collective and considered opinion of this Council upon this Bill, he thought it would be well to appoint a committee this session to consider and compare it with other Bills and report on the whole question in November.

Dr. MCVAIL moved, as an amendment, that the Council proceed to consider the Bill during the present session. His opinion was that after what had occurred—the Council having asked the Privy Council whether they wished their opinion this session and having got this quite decided and emphatic reply—there was no other course open to them.

Mr. BRUDENELL CARTER said that in the light of experience he doubted whether the formation of a committee would be of any use in this matter. When the committee had considered the Bill and made their report that report would be discussed clause by clause, probably in committee of the whole Council, just as if the committee had never sat.

Dr. PETTIGREW thought the Council were bound, after having approached the Privy Council in the way they had, to act at once.

Dr. RENTOUL said that after hearing the statement of the Privy Council representative (Dr. McVail) he would ask leave to withdraw his motion.

This motion was by leave withdrawn and Dr. McVail's amendment became the motion before the Council.

Dr. GLOVER moved, as an amendment to this, that the Midwives Bill referred to in the letter from the Privy Council be referred to a committee for consideration and report to the November meeting of the Council.

Dr. MACALISTER seconded the amendment.

The PRESIDENT said it would be a most expensive matter for the Council to deal now with the Bill. It would occupy four or five days and cost £400 or £500, and he was certain the Bill would not pass this session.

Dr. RENTOUL: Do I understand that the discussion of this Bill would cost £400 or £500?

The PRESIDENT: Yes; the cost is about 100 guineas per day.

Dr. RENTOUL: I think it is very cheap.

On a division being taken Dr. Glover's amendment was carried by 16 votes to 11, and became the finding of the Council.

The Case of Robert Alexander Douglas Lithgow.

The Council deliberated for over an hour on the case of Dr. Douglas Lithgow, the hearing of which had proceeded during the latter part of the previous sitting. At the conclusion of the deliberations it was resolved:—

"*a.* That the Council do proceed at once to pronounce its judgment on the case. *b.* That the first charge made against Dr. Robert Alexander Douglas Lithgow has been proved to the satisfaction of the Council. *c.* That the second charge made against Dr. Robert Alexander Douglas Lithgow has been proved to the satisfaction of the Council. *d.* That the Council do now judge Dr. Robert Alexander Douglas Lithgow to have been guilty of infamous conduct in a professional respect, and do direct the Acting Registrar to erase from the Medical Register the name of Dr. Robert Alexander Douglas Lithgow."

Strangers and Dr. Lithgow having been re-admitted, the PRESIDENT announced the finding of the Council.

The Case of Edmund Evance Hooper.

The Council, with Sir William Turner in the chair, proceeded with the consideration of the case of Edmund Evance Hooper, of Bridport-place, New North-road, N., registered in England on Jan. 1st, 1859, as Mem. R. Coll. Surg. Eng. 1841, Lic. Soc. Apoth. Lond. 1841, who had been summoned to answer the following charge, as formulated by the Council's solicitor, under the direction of the Penal Cases Committee, acting on a report by Dr. Wynn Westcott, coroner for the North-East District of London:—

"That, being a registered medical practitioner, he authorised, permitted, and enabled an unqualified person named Frederick Taylor, under cover of his name and qualifications and assistance, to carry on medical practice as though he were duly qualified, and to perform the duties and exercise the functions which by law are confined to qualified and registered medical practitioners."

Mr. Hooper, who is eighty years of age, and who has been in actual practice for half a century, appeared before the Council unaccompanied either by solicitor or counsel. The charge was read by Mr. Farrar, and Mr. Muir Mackenzie read the evidence, which consisted of depositions made at an inquest held last December in the coroner's court at Shoreditch on the body of a boy named Bertram Lott, who was seen some five times by the Frederick Taylor named in the charge after an accident followed by blood-poisoning. These depositions showed that for the five visits Taylor had been paid 3*s*. This man, in his deposition in court, stated that he was not a registered practitioner, and the practice he took charge of belonged to Mr. Hooper, who saw cases with him often. The practice, Mr. Hooper admitted before the coroner, was his. It had been his son-in-law's, and when his son-in-law (Mr. Watt) died he thought he might take it over, as it was near his surgery at Bridport-place. Taylor had assisted Mr. Watt, and he kept him on. He visited the shop, which was at 240, Hoxton-street, every day; and not only was he unaware that Taylor's name ever had been on the window, but he did not know that it was contrary to the rules of the General Medical Council to carry on the practice in the way he was doing.

Mr. HOOPER, in answer to a request for explanations, presented himself for examination. He said that as Mr. Watt had carried on the practice with Taylor's assistance for a long while without notice being taken, he supposed it was quite right for him to continue in the same way.

The CHAIRMAN: Have you no knowledge of the action taken for some years by this Council in connexion with unqualified assistants?

Mr. HOOPER: Not the slightest.

The CHAIRMAN: Do you never read the medical journals?

Hosted by Google

Mr. HOOPER: Very seldom. My time is so much taken up.

By Dr. RENTOUL: He supposed Taylor was registered when he was a student. Taylor was now about thirty-five years of age, and had been a medical assistant for some fifteen years. He had been unable to finish his medical course because of his father's death and the want of funds. He was paid a salary of £2 10*s.* a week. He never gave death certificates and never went out to new cases at night.

Dr. MACALISTER: There was only one book of certificate forms and he kept that himself. He never provided Taylor with certificate forms. He himself had advised the coroner of the boy Lott's death. He never had any accounts to send out. The fees were collected without accounts.

Dr. RENTOUL: You charge 7½*d.* a visit. That is about the rate of 3*s.* for five visits. Is that the ordinary fee for your district?

Mr. HOOPER: It is a low fee. I suppose it included medicine.

By the CHAIRMAN: He lived in Brunswick-square, which was about two miles from his surgery. He went there because he wanted to avoid being called out at night, as he found his health was beginning to suffer from going out at night. He boarded at Brunswick-square.

By Dr. MACALISTER: He was the tenant of 240, Hoxton-street, and he had rent to pay for three different premises.

By Dr. GLOVER: Taylor attended midwifery cases at night alone if the cases had been previously undertaken, but he (Mr. Hooper) visited the patients later.

By Mr. MUIR MACKENZIE: He was at Taylor's call in his surgery till half-past nine o'clock at night. Taylor accepted all the money that was brought to 240, Hoxton-street, and accounted for it to him (Mr. Hooper). He never had anything to do on his own account.

Mr. HOOPER, in answer to other questions, said that Taylor had been at the Council's offices that day, but had been obliged to go away. Taylor's character was so good in every respect and he had so much knowledge of his profession that he (Mr. Hooper) did not think the poor people could be in better hands, and he should not have the slightest objection to call him in if he himself were ill. Taylor might be called Dr. Taylor. The people of the neighbourhood were strange in their use of the word "doctor." While they would call him (Mr. Hooper) "Mr.," they would call an ordinary druggist "doctor."

After deliberating in private the Council found the charge proved to their satisfaction, but they postponed further consideration of the case till Monday.

Disciplinary or Penal Powers of the Qualifying Medical Authorities.

Mr. BRYANT submitted an *interim* report by the Executive Committee on the Disciplinary or Penal Powers of the Qualifying Medical Authorities. This report contained a narrative in regard to what has been done on the subject. It showed that communications had been received before the end of last November Session which could be summarised as follows:—

(*a*) FROM UNIVERSITIES AND OTHER BODIES CONCERNED.

University of Durham.—The report of the Executive Committee on the Disciplinary or Penal Powers of the Qualifying Medical Authorities, with Appendix, would be considered.

Victoria University.—Inquiries were being made which it was hoped would lead to some satisfactory result.

University of Edinburgh.—Powers could not be obtained by application to the Privy Council, and the University Court was not disposed in the meantime to obtain such powers either from the Commission or by statute.

University of Aberdeen.—The Scottish Universities Commission had already been approached and would be again.

University of Glasgow.—A change by means of fresh powers from the Legislature, to remove temporarily or permanently convicted graduates, was anxiously desired, but there were insuperable difficulties. By a future Bill it might be required that all qualifications should be suspended during the absence of a name from the Medical Register.

University of St. Andrews.—The University Court would coöperate with the other Scottish University Courts in obtaining powers.

Royal University of Ireland.—The report would be considered.

Apothecaries' Society of London.—It would be useless to apply to Parliament for a new Act at present, but the Society would be willing to do so at a suitable time.

Apothecaries' Hall, Dublin.—The report would be considered.

University of Cambridge.—Disciplinary statute obtained from Privy Council enabling the University to deal with graduates guilty of offences punishable by imprisonment, that being all that it was possible to obtain.

(*b*) From the SCOTTISH UNIVERSITIES COMMISSIONERS.

The matter was outside their province and no action could be taken.

(*c*) From the PRIVY COUNCIL.

The Privy Council was prepared to consider applications from chartered bodies, and the other bodies could proceed by statute.

The report further showed that before the November session terminated the Executive Committee informed the Council that it would continue to give its best attention to the subject, and in furtherance of that object had reappointed its sub-committee with Sir Dyce Duckworth in the place of Sir Walter Foster. On April 15th last, by the direction of the sub-committee, further inquiries were made, in answer to which, and to the previous inquiry of the Council, communications had since been received from which it would appear that as some of the licensing bodies are engaged in seeking for further disciplinary powers, the General Medical Council should in the meantime defer action until the result of the applications by these bodies had been ascertained.

Mr. BRYANT, in moving that the report be received and entered on the minutes, said that if the universities could not individually obtain the powers desired, the Council must find some means of getting it for them, and until it was got the committee could not present a full report.

Dr. MCVAIL mentioned that he was a member of the committee of the University of Glasgow, who sent the communication proposing that the Council should ask for an amendment of the Medical Act which would give the University power to suspend the qualifications of any of their medical graduates during the absence of their names from the Medical Register. He did not know at the time that communication was forwarded that the very power recommended was provided as regards dentists in the Dentists Act. The last paragraph of Clause 13 of that Act provided that "any name erased from the Register in pursuance of this Section shall also be erased from the list of licentiates in dental surgery or dentistry of the medical authority of which such person is a licentiate." While this provided for erasure, Clause 14 provided for restoration on restoration to the Register.

Mr. BRYANT: That is precisely what we want.

Dr. MCVAIL: That is what the Committee of Glasgow University want.

Mr. BRYANT: That is probably the action we should take if we are to do anything.

Dr. MCVAIL: The Executive Committee might bring up a definite proposal next November to make the Medical Act in this matter the same as the Dentists Act.

Mr. BRYANT said it was three sessions ago since the subject was referred to the Executive Committee. He brought up a report in the committee with a recommendation of the automatic kind Dr. McVail had just referred to, in entire ignorance that it already existed in the Dentists Act. Their counsel had given the opinion that they should seek for the power, but the President opposed it very strongly, and they were unable to bring before the Council a report which he supposed was still to be found in one of the pigeon-holes in the office.

Dr. CHURCH did not think this was the right moment to go into a debate on this subject, but he should be sorry to think that any clause of the Medical Act could act automatically, as Dr. McVail supposed. It was quite conceivable that men might have to be struck off the Medical Register for having committed crimes or misdemeanours which came under the Medical Act, and therefore called for the necessity of striking them off the Medical Register which the University might think would not be such as to justify them in depriving these men of their university medical degrees. Consequently, on behalf of Oxford University he should have to oppose any proposal for the enactment of the automatic powers of the kind in question.

Dr. GLOVER moved the adjournment of the debate.

Sir DYCE DUCKWORTH seconded the motion, which was agreed to.

The Council then adjourned.

SATURDAY, MAY 29TH.

The Council continued its session to-day.

The Examinations for Dentists.

Mr. THOMSON asked and at once obtained leave to call attention to certain passages in Mr. Tomes' report on the examination for the diploma in dentistry of the Royal College of Surgeons of England, and to invite an explanation from the representative of the body. Mr. Tomes said that the general conduct of the examination, the scope and the suitability of the questions asked, and the methods of marking adopted, left little to be desired, and the Dental Education and Examination Committee in their report, which was signed by Mr. Bryant as chairman,

Hosted by Google

said that they regarded this report as a valuable one, and asked the Council to bestow upon it very close attention. The committee also said that the alterations both in the curriculum and course of examination appeared to be in the right direction, and they believed many of them were worthy of adoption. This report, along with the others, had been sent down to the various dental licensing bodies, and therefore it was not unlikely that they might consider the question whether they ought not to model their examinations upon this one of the Royal College of Surgeons of England. Now he asked the attention of the Council to one or two points in the report of the examination in surgery. Questions were asked on the treatment of paratoid fistula, tongue-tie, and its treatment, removal of the tongue, sebaceous cyst of the scalp, dermoid cyst, wound of the radial artery, gummata, and the stages of syphilis and their treatment. He wished to know from Mr. Bryant, as chairman of the committee and the representative of the Royal College of Surgeons of England, whether he thought this an examination suited for gentlemen who were seeking a qualification as dentists pure and simple. If they were to proceed upon these lines they would be putting the dentist into a much better position than the licentiates or members of any college of surgeons in the three kingdoms, because they were not only testing his capacity to deal with the whole subject of dentistry, but they were enlarging his powers to the recognition and treatment of syphilis and the treatment of sebaceous cyst of the scalp. He failed to see the connexion between the scalp and the teeth or between syphilis generally and the teeth. He could understand that certain syphilitic sores about the mouth might be recognised and examined upon, but upon the general question of the stages of syphilis and the treatment thereof he thought this Council ought to say something with regard to limiting the scope of the examination. They were apparently about to create a new order of practitioner—gentlemen who were to be dentists and who were to know a great deal of what the general surgeon knew—in fact, to make a class of practitioner who in some respects were to be superior to the ordinary members and licentiates of the various surgical corporations. He therefore thought it was a matter of urgency.

Mr. BRYANT said it was the case that the Dental Education and Examining Committee had said in their first report that the report of Mr. Tomes on the examination of his College was a very valuable one, and that they asked the Council to bestow upon it very close attention. The committee felt that the line which his College had adopted in the way of examinations was good, and although they were not prepared then to recommend to the Council a scheme drawn up very much on the lines adopted by his College they thought it would be right to call the special attention of the other dental examining bodies to what the Royal College of Surgeons of England had done, so that they personally might frame their own schemes somewhat in the same line. In the second report of the committee many of the arrangements adopted by his College had been included. He would make no comment on, and he raised no objection to, the remarks which Mr. Thomson had offered with respect to the examinations of his College. It was quite right that Mr. Thomson should call the attention of the Council to the subject. Of course, for a dentist to talk about the removal of the tongue or the treatment of sebaceous cyst of the scalp seemed to be a little beyond his province. At the same time, if one put down a series of questions given at any examination there was never the slightest difficulty in raising objection to one or two of the questions. In this case they had a large series of questions, and he thought, upon looking through them, that they were, on the whole, quite satisfactory. He was pleased, however, to have his attention called to the matter and he would put it before the College.

The Disciplinary or Penal Powers of the Bodies.

Dr. GLOVER then resumed the debate on the motion proposed by Mr. Bryant and seconded by Dr. MacAlister, "that the interim report by the Executive Committee on the disciplinary or penal powers of the qualifying medical authorities be received and entered on the minutes." The Council, he said, were greatly indebted to the Executive Committee for what they had done in this connexion. They had put the disciplinary functions of the bodies into very plain form and given them a prominence from which they could not recede. He had the less scruple in complimenting the committee because, although he was now a member himself, he was only a recent member and had had no share in this work. The ethical standard of the profession was of great importance to the public. Scarcely a day passed without their being reminded of that in the public prints and in the law-courts, and the public looked to the Council primarily and to all the qualifying medical bodies together and singly to sternly maintain the ethical standard of the profession. And the profession looked very much to the Council and to these bodies for doing the same thing. It was satisfactory to find that on this subject there was almost entire unanimity among the qualifying bodies. The only exceptions were the University of Cambridge and his own University—that of Edinburgh. With these exceptions the bodies were agreed that they should have powers of the kind proposed. This prominence of the subject and this unanimity of the bodies on this opinion led him to hope that the Council would accept the slight amendment of the report of the Executive Committee which he was going to propose.

Sir WILLIAM TURNER, who in the temporary absence of the President was acting as chairman, said it might be well if Dr. Glover told the Council what he was going to propose.

Dr. GLOVER said he would do so. They would find in the report that the Executive Committee said that the Council should in the meantime defer action until the result of certain applications by bodies had been ascertained. Now he would read what he proposed to substitute.

The ACTING CHAIRMAN pointed out that this was the whole report of the committee, and that all else was mere narrative, and the question before the Council was that the report be received and entered on the minutes.

Dr. GLOVER said he had no objection to this report being received and entered on the minutes, but he did object to it being taken as a full expression of the mind of the Council.

The question was then put from the Chair that the report be received and entered upon the minutes, and it was at once adopted.

Dr. HECTOR CAMERON moved that the report be referred back to the Executive Committee for further consideration. He understood that Dr. Glover was a member of the committee, and he would, therefore, be able to raise before the committee the questions he now proposed to raise.

Dr. MACALISTER said he would be prepared to second this if the whole subject was to be referred back to the committee.

Dr. GLOVER said this did not quite meet his views. He wanted to know whether this short report, stopping all further action by the Council, was really the mind of the Council. He would, therefore, propose that the Council at once proceed to discuss this report.

Sir DYCE DUCKWORTH seconded this amendment.

Dr. RENTOUL thought this an urgent matter. During the present session they had removed from the Register a graduate of St. Andrews University, and in the present state of things he could continue to have on his doorplate "M.D. of the University of St. Andrews." If they were not to make themselves a public laughing-stock they must take action.

Dr. MACALISTER said that no amount of discussion would give the University of St. Andrews power to deal with its graduates. The University of St. Andrews had expressed its willingness to apply for powers, and really the thing was not mature until they had got the answers from all the bodies.

Dr. GLOVER said there were good reasons for the continued discussion of this report. They had got strong replies from two bodies which he thought should be immediately answered by this Council. They were at the stage of correspondence—friendly correspondence—upon this subject, and unless they hurried on they would never get it settled. If the Council thought the replies of the Universities of Cambridge and Edinburgh quite unanswerable, that, of course, was another matter. His contention was that they admitted of a very strong answer and that they called for an immediate one. The University of Cambridge said by Professor Clifford Allbutt: "I am to inform you on behalf of the Special Board of Medicine in this University that it is not proposed to seek any further extension of our disciplinary powers in respect of the moral character of our graduates in medicine. I will not trouble you with our reasons unless you desire it; but I may say that in our opinion the guilds of the profession—the Colleges of Physicians and of Surgeons for example—are the proper bodies to keep up a continuous standard in the ethics of the profession." A man might be upon the Medical Register with no other qualification than that of the University of Cambridge. He might do all manner

Hosted by Google

of discreditable things, infamous in every respect, professional and otherwise; and unless the university got the power to remove him he would still, according to the opinion of lawyers, continue to be qualified, and the members of his profession would be entitled to meet him. He contended that if the universities were to license men they must take the responsibility of looking after them when they were licensed, and a college of physicians or surgeons could not be answerable for the conduct and character of the university graduates. That was, in his opinion, an unanswerable reply. Now he came to his own University—that of Edinburgh—which stood alone in this matter among the Scottish universities. Unless the Council replied to the University of Edinburgh, that body would say there was no reply and that silence gave consent to their letter. In this letter the University Court said they had resolved to take no action in the meantime to obtain the proposed powers either from the Scottish Universities Commission or by statute. In a letter dated July 18th, 1896, the secretary of the Scottish Universities Commission said that the matter was considered by the Commissioners some time ago at the request of the University of Aberdeen, and they were of opinion that if the universities did not already possess the power of dealing with their graduates the Commissioners could not confer the power, and they therefore decided to take no action in the matter. They further said they were of opinion that it was not their province to move the Privy Council with regard to matters which did not fall directly within their powers.

Dr. HERON WATSON (who is one of the Commissioners): Hear, hear.

Dr. GLOVER said this showed that the Commissioners had no intention of going on with this subject, and their opinion was that it did not come within their province. But the Commissioners did not appear to have had before them the opinion of the Lords of the Privy Council. This Council had the entire sympathy and support of the Lords of the Privy Council. The Lords of the Privy Council, in a letter dated July 7th, 1896, stated that they would be prepared to consider applications from the chartered medical bodies for supplementary charters granting disciplinary powers similar to those conferred upon the University of Cambridge, and the other licensing bodies could, if they thought fit, proceed by statute or in the case of the Scottish Universities by ordinance. This was a suggestion to the Scottish Universities Commission, and he wanted to move the President of this Council to bring under the notice of the Commissioners this opinion of the Privy Council.

The PRESIDENT (who had now returned, but had not resumed his place in the chair): The President of the Council cannot and will not do it.

Dr. GLOVER: I am sure I know Sir Richard Quain better than he knows himself, and that if this Council request him to do it he will do it.

The PRESIDENT: But he has no power to do it.

Dr. GLOVER, continuing his speech, said that the situation, therefore, was that on the one side they had the sympathy of the Privy Council and on the other the obstructive attitude of the University of Edinburgh, which he felt certain could not be a final attitude. They had heard something recently about the decadence of the Scottish universities. He had no belief in that decadence. He believed it was the destiny and the duty of the universities of Scotland, and especially of the University of Edinburgh, to take a most conspicuous part in the educating and qualifying of the medical practitioners of this country and this empire, and upon these grounds, and because he was a graduate of it, he the more regretted that Edinburgh should differentiate itself from the other universities of Scotland, and show any attitude of indisposition or *non-possumus* upon this important matter. He hoped, therefore, that the Council would agree with him that they had already material to be answered.

Mr. BRUDENELL CARTER said he wished to point out that the sympathy of the Privy Council which Dr. Glover had laid stress upon was limited to assisting other bodies to obtain the same power that had been conferred upon the University of Cambridge, and that power Dr. Glover had pronounced to be wholly insufficient.

Sir DYCE DUCKWORTH said that his object in seconding the amendment was simply to drive home to the authorities of the Scottish universities that the Council was strongly in earnest, and would do its utmost to move these authorities to take action in the matter. The Council would not accept a *non-possumus* from any body in this matter. He considered that these powers ought to exist in the best interests of the public and of the profession.

The amendment was then put to the Council and negatived, and the motion of Dr. Cameron carried.

Mr. BROWN said he desired to move another motion, that a copy of the letter of the Privy Council be sent to the Scottish Universities Commission calling their attention to the powers they possessed of dealing with this penal question by way of ordinance. He felt strongly that this matter should not be delayed for a single day. It was of little use that the Council should occupy its time in hearing penal cases if the men were allowed to hold their diplomas and parade them before the public. He would move that a courteous request be made to the Scottish Universities Commissioners to carry out the suggestion contained in the letter of the Privy Council.

The ACTING CHAIRMAN: Will Dr. Heron Watson kindly tell us when the Scottish Universities Commissioners go out of existence?

Dr. HERON WATSON: It is a doubtful matter, but it is before the end of this year and nothing can be done by them.

Dr. BATTY TUKE: This resolution would probably put them out of existence a little sooner.

The PRESIDENT suggested that the motion of Dr. Cameron might be put, with the addition of words providing that the Executive Committee should take such steps as they thought necessary.

Mr. BROWN thought there should be an authoritative resolution from the Council. It was clear that there was no intention whatever on the part of these university bodies to carry out the wishes of the Council. He was very much struck by the observation made yesterday by Dr. Church that a person might be struck off the Medical Register for infamous conduct in a professional respect or for a misdemeanour and might still be a desirable person to remain a member of his university. He did not know what the desire of university men might be as to the company they kept.

Dr. CHURCH, interrupting, said he said nothing of the sort. What he said was that it was quite conceivable that men might have to be struck off the Medical Register for having committed crimes which came under the Medical Acts, and therefore necessitated this Council striking them off, but which a university might not hold to be such as to justify the university in depriving them of their degrees.

Mr. BROWN said this was a very acute and subtle distinction, but he was quite willing to accept it, and it made no difference to his argument. He saw no reason why if, under the Medical Act, a man was struck off the Register his university should not be compelled to withdraw his medical diplomas.

Dr. RENTOUL seconded Mr. BROWN'S motion.

The ACTING CHAIRMAN said that if he had been sitting at the table he should have had something to say about this matter, but perhaps he would be allowed a few words. The Scottish Universities Commissioners had told the Council plainly that they had no power to deal with the matter by ordinance, and how could the Council, by transmitting this letter of the Privy Council to them, expect them to alter this opinion which had been arrived at after most mature consideration? It seemed to him that the Council would be putting itself into a very unfortunate position.

Sir DYCE DUCKWORTH asked whether they were to understand that the Privy Council had made a mistake.

The ACTING CHAIRMAN said that apparently they had made a mistake.

Dr. GLOVER asked whether the letter of the Privy Council had been communicated to the Scottish Universities Commissioners.

Mr. BRYANT replied that he did not think it had.

Dr. GLOVER said that in these circumstances he thought it a reasonable request that it should be forwarded to them without delay. High as was the authority of the Scottish Universities Commissioners, the authority of the Privy Council was still higher.

Dr. MACALISTER said it might be that the Privy Council had not looked into the matter.

Dr. BATTY TUKE pointed out that the Commissioners included among their number very great lawyers, and had weighed the thing carefully and knew exactly what were their duties. Dr. Glover had, however, been acting under a false conception. He thought that the various universities were willing to go the length of depriving a man of his

Hosted by Google

degrees for any offence he might be found guilty of by the Council. He (Dr. Tuke) did not believe there was a university in the country which would ever ask such powers. All they would ask for was the same powers as had been granted to the University of Cambridge and nothing more.

Mr. BROWN asked leave to modify his motion to a simple instruction to send a copy of the letter of the Privy Council to the Scottish Universities Commissioners for their information.

The ACTING CHAIRMAN said this could do no harm if it did no good. The motion thus modified was put to the Council and rejected by 12 to 11 votes.

The Registrarship.

The Council, with the PRESIDENT in the chair, sat *in camerâ*, and came to the following resolutions, which were made public on the re-admission of strangers :—

"1. That a gratuity of £1000 be given to Mr. Miller, the retiring Registrar. 2. That Mr. Allen, the Assistant Registrar, receive a gratuity of £75 for his extra services during the past six months. 3. That in future the appointment of General Registrar be an annual one, and that he be eligible for re-appointment. 4. That the salary attached to the office be £500 per annum, to be apportioned according to the standing orders. 5. That Mr. H. E. Allen be appointed General Registrar under the Medical and Dentists Acts for a year from June 1st, 1897. 6. That the office of Assistant Registrar be abolished as from June 1st, 1897. 7. That the General Registrar attend at the office from 10 till 4 on Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays, and from 10 till 2 on Saturdays, and at other times when necessary, and that he shall not absent himself from his duties unless with permission from the President or one of the Treasurers. 8 That the Executive Committee amend the standing orders in accordance with the above resolutions."

Tropical Diseases.

Dr. LEECH moved the following motion, notice of which had been given by Dr. Bruce :—

"That the attention of the licensing bodies be called to the urgent necessity of more particular attention being paid by students of medicine to the subject of tropical diseases."

He said he moved this resolution as being in accordance with the spirit of the times. They were recognising more and more every year that there was a greater Britain as well as a Great Britain. To the Britain beyond the seas we not only sent many people who chose to stay, but a large number of medical men educated in the home schools. But very little was done for the latter's education in tropical diseases, and in the examinations questions were never put on the subject, except, of course, for those of medical men going on military service, who were obliged to know something of such diseases. It seemed to him that this was a thing that should not go on. If a few questions were occasionally put it would show students that they should have some knowledge of tropical diseases, and instead of totally neglecting the subject, as they practically did now, they would feel themselves obliged to pay some attention to it. It might be said that medical men would get knowledge of these diseases when they went out to the tropics. So they would, but it would be at the expense of their earlier patients. It might be also said that the proposal was only the expression of biased opinion, but biased opinion was sometimes very valuable. Again, it might be urged that this would increase the student's work, but if it enlarged his knowledge of tropical diseases his work should be increased.

Mr. BRUDENELL CARTER seconded the motion. He thought that if it were carried and the qualifying bodies interjected occasional questions into their examinations, students would come to see that it would pay them to give some attention to the subject.

Sir DYCE DUCKWORTH said it was a question how far this motion was a practical one. Of course, the opportunities afforded to British students in these islands of seeing tropical diseases were really very limited. In this metropolis of the Empire a very small portion of these diseases came under observation. The largest school that afforded sight of them was Greenwich Hospital, where sailors frequently arrived suffering from diseases of a tropical origin. A few cases found their way as far as Guy's Hospital, but very few indeed were ever seen in the other large London hospitals; yet in respect to the whole matter of tropical diseases he felt sure that much greater attention was now being paid to the subject than formerly. This was especially the case in regard to malarial fever, and the true nature of malaria was now taught to the ordinary student. What he feared was that if this Council called the attention of the examining boards to the matter they would be told that they had done the like before in recommending special attention to special diseases, and there was nothing very practical likely to come out of it. In two of the London hospitals—Guy's and St. George's—there were lecturers on this subject who had had experience of it in India and elsewhere abroad, but as yet tropical diseases was not a compulsory subject, and, so far as Greenwich Hospital was concerned, although the demonstrators were willing to afford information when it was sought, it was not taken advantage of to any great extent. Still, the subject had been called attention to of late years, and the average student, he thought, was beginning to give a little more attention to it.

Dr. MACALISTER hoped Dr. Leech would be satisfied with having brought forward the subject and that he would not press it further. He should not like the licensing boards to have a proposal of this kind forwarded to them at the present moment. The language of the motion was somewhat exaggerated. They could not give evidence that there was any urgent necessity for this, because of late years it had been said the necessity had been growing less year by year.

Dr. LEECH was quite willing to withdraw "urgent."

Dr. GAIRDNER said he entertained very much the kind of opinion that Dr. MacAlister had expressed, but he put it a little more strongly. The tendency of sending this motion out to the licensing bodies would be that the bodies would regard it as a loading of the curriculum with more systematic work of a kind that could not be illustrated by cases in their own hospitals. The true principle of teaching the use of medicine was the teaching the principles of it with reference to cases that they actually had before them, and to depart as little as possible from practical work. He, therefore, would not like to have the curriculum loaded with a new subject of this kind.

Dr. PETTIGREW was of the opinion that the motion really amounted to adding a new subject to the curriculum, and they should be very careful in regard to that. They had been tinkering at the curriculum for the last twenty years, and it would be a pity to let any statement of the kind contained in the motion go out from the General Medical Council with any show of authority, for he believed it would have a very bad effect. It would injure the curriculum more or less, and it might discourage the student. No one could underrate the importance of a knowledge of tropical diseases among the students of a country like Great Britain, but he understood that the subject was not overlooked at the present time. It was the duty of the teacher to deal with principles and ground the student, and let such things as these tropical diseases come into his experiences. He hoped Dr. Leech, having ventilated the subject, would withdraw the proposal, as this was a somewhat unfortunate time to proceed with such a motion.

Dr. LEECH, while pointing out that it was not proposed to increase the curriculum, the intention being merely to secure the introduction in examination papers of an occasional question that would draw the students' attention to the matter, said he would be glad to withdraw the motion if the Council wished it.

The motion was then withdrawn.

A New Member's Undertaking.

Before the adjournment Sir WILLIAM TURNER mentioned that there was nothing on the business programme that would necessitate the present sittings of the Council going beyond Monday.

Dr. RENTOUL said he had been asked to present the petition of Mr. R. B. Anderson which appeared on the paper and move a resolution. The due consideration of the case would take two days. It was his duty to present the petition.

The PRESIDENT: You need not trouble. We have decided it already. It is entirely outside our authority.

Dr. RENTOUL: I should like, with all due respect to the chair—

The PRESIDENT: But we have nothing to do with it.

The Council adjourned till Monday.

MONDAY, MAY 31ST.

The Council met again to-day and completed the business of the session.

The Registrarship.

There was read a letter from Mr. H. E. Allen accepting the Registrarship and one from Mr. W. J. C. Miller thanking the Council for the resolution passed with reference to him.

Hosted by Google

The Apothecaries' Hall of Dublin.

Mr. Bryant, chairman of the Committee on the Appointment of Assistant Surgical Examiners to the Apothecaries' Hall of Dublin, presented the following report, viz. :—

"1. Resolved:—That the committee do recommend to be assistant examiners for a period of two years Mr. Arthur Chance, F.R.C.S. Irel., L.A.H. Dubl., L.M. Coombe Hosp. Dubl., and Mr. Henry Alexis Thomson, M.D. Edin., B.Sc., F.R.C.S. Edin., M.R.C.S. Eng.

"2. That the remuneration of these examiners, for each assistant examiner be 5 gs. per diem while engaged in the examination, with expenses calculated on the scale of charges allowed by the General Medical Council for its members (Section 5, Sub-section 3, Medical Act, 1886).

"3. Also resolved:—That it shall be the duty of the said assistant examiners to secure at the said examinations the maintenance of such standard of proficiency in medicine, surgery, and midwifery as is required under the foregoing provisions of this Act (1886) from candidates at qualifying examinations, and for that purpose the said assistant examiners shall have such powers and perform such duties in the conduct of these examinations as the General Council may from time to time by order prescribe; and any examination held subject to the provisions of this section shall be deemed to be a qualifying examination within the meaning of this Act. (Section 5, Sub-section 2.)

"[The Medical Corporation shall have power to admit to its examinations assistant examiners appointed under this section, and to conduct its examinations in accordance with the requirements of this section, and of any orders made thereunder, anything in any Act or Charter relating to such Corporation to the contrary notwithstanding.] Section 5, Sub-section 4, Medical Act, 1886.

"4. Resolutions suggested to be made under Section 5, Sub-section 4, Medical Act, 1886, in regard to the conduct of examinations made in accordance with the above section, and now submitted for approval to the Council:—

"The Examination in Surgery should include:

A written paper on printed questions.

A Clinical Examination, with or without a written report on a case.

Operative Surgery.

An Oral Examination, with the use of pathological specimens.

"5. The duties of the said assistant examiners to secure at the said examinations the maintenance of such standard of proficiency in Medicine and Midwifery shall be as follows:—To inspect the Examinations in Medicine and Midwifery, so as to ascertain whether they conform to the scheme above laid down for the Examination in Surgery, and to satisfy themselves that the standard of proficiency is of equivalent value."

The report was received and entered on the minutes.

Mr. BRYANT then moved, and Mr. TICHBORNE seconded, the adoption of the first resolution of the committee.

Mr. BROWN said he was very much dissatisfied with this arrangement. He thought the Council were entitled to information as to the reason why the gentlemen put forward by the Apothecaries' Hall were not now proposed.

The PRESIDENT pointed out to Mr. Brown that the matter had been very fully considered by the committee and that this recommendation came from the committee, and was moved by its Chairman and seconded by Mr. Tichborne, the representative of the Apothecaries' Hall of Dublin.

Mr. TICHBORNE said it was only right he should state that the Hall had every confidence in the gentlemen they proposed, and he had only given way to the strong opinion of the committee. Let the Council understand that he did not withdraw their names.

The motion was then adopted, as was also a motion incorporating the second recommendation.

Mr. BRYANT said with regard to the third and fourth clauses of the report that they had caused the committee a great deal of trouble and had been drawn up by the committee under the firm conviction that it was necessary to do so. But since coming into this room he had been assured by the President that they had gone *ultra vires* in proposing them, and that view was supported by Mr. Farrer, the Council's solicitor.

Dr. MACALISTER moved, as the best way out of the difficulty, that it be remitted to the Executive Committee to inform the Assistant Examiners as to their duties, and Mr. BRYANT seconded this motion.

After some discussion this motion was agreed to.

The Scotch Public Health Bill.

Dr. THORNE THORNE, chairman of the Public Health Committee, moved that the following report from that committee be adopted as expressing the opinion of the Council, viz. :—

"1. The attention of the General Medical Council having been called to a proposed modification of Clause 22 of the Public Health (Scotland) Bill, they cannot do otherwise than view with grave apprehension the proposal to place the opinion of the sanitary inspector, in matters where a judgment has to be formed as to what is or is not liable to constitute a danger to public health, on a statutory equality with that of the medical officer of health.

"2. The General Medical Council would recall the fact that the legislature have from time to time extended, by statutory enactment, the requirement that medical officers of health should before their appointment give definite evidence of the possession of special acquirements fitting them for their public duties, and that the General Medical Council have spent much time and expense in requiring and maintaining at a high standard a scheme of education and examination that shall give effect to the intentions of the Legislature.

"3. And the General Medical Council feel convinced that if the opinion of officers, altogether without the requisite technical and professional training, is to be placed on a similar footing to that of medical officers of health, the efforts of the Council to ensure the requisite distinctively high standard of efficiency in the Public Health Service will be seriously frustrated."

He explained that this matter had been brought to their notice by a petition from the Society of Medical Officers of Health in Scotland, who objected to certain changes which were being made in the Bill in its passage through the Grand Committee of the House of Commons on Law.

Dr. PETTIGREW, in seconding the motion, said that if the sanitary inspector was to occupy the same position in settling sanitary matters as the medical officer, then all the Council had been doing of late years in building up an elaborate system of sanitation pretty much went by the board. This, in his opinion, would be a great calamity, because every one knew that nowadays sanitation was one of the most important things that medicine had to deal with. No doubt county councils and others in authority would like to see the sanitary inspector vaulting into the saddle of the medical officer of health. It would probably get them out of many difficulties, and save them both money and time, but they could not pretend that a sanitary inspector was a man of any medical training. He had heard from a Scotch Member of Parliament that there was a strong disposition on the part of the Government to force the sanitary inspector upon them, and he therefore hoped the Council would support the medical officers of health in Scotland to the very utmost of its power.

Dr. GAIRDNER said he had written to Lord Balfour, the Secretary for Scotland, telling him that the Grand Committee were spoiling his Bill. All this had come about in a committee, a good many of the members of which had a very imperfect knowledge of the subject, and others had the object of pressing points in order to economise and cheapen public health administration in Scotland. It was quite evident that the state of things in England differed from that in Scotland. In most of the districts in England where a medical officer of health exists he had really got a firm grip of the whole business of initiating proceedings, and he took care that they were not initiated by other and less skilled hands without his knowledge. In Scotland, however, it seemed to be the sanitary inspector who was chiefly employed by the local authorities. If this process went on in the Committee of the House of Commons, what he would recommend Lord Balfour to do would be to drop the Bill altogether and bring it up in another form in another year.

Dr. CHURCH said he felt sure the University of Oxford would be glad if the Council took the proposed action in this matter.

Sir DYCE DUCKWORTH, Dr. MACALISTER, Dr. BATTY TUKE, Dr. REID, and Dr. WATSON having spoken in the same line, the motion was adopted by the Council.

It was agreed that copies of the report should be sent to the Secretary for Scotland, the Lord Advocate, the members of the Grand Committee, and the signatories to the petition.

The Employment of Unqualified Assistants.

Dr. MACALISTER moved:—

"That it be referred to the Executive Committee to consider whether the Council's resolutions on the employment of unqualified assistants, as they appear in the advertisements inserted in the medical journals, may not with advantage be rendered clearer and more stringent."

He said it was extremely difficult indeed to extract from these advertisements a clear idea of what it was exactly that the Council objected to in relation to covering, and he thought they might be greatly improved. As to the resolutions of the Council being made more stringent he thought he might say that the feeling of the Council had grown in regard to this matter, and it was becoming nearly time for them to say that they would put a stop if they could to the employment of unqualified assistants in the treatment of patients altogether. They had hitherto said that unqualified assistants were not to be unduly used, or wrongfully used, or carelessly used, and it must have become apparent to members who had sat through these trials that the unqualified assistant as such must go; he was a perpetual source of temptation to the practitioner who desired to be just within the lines of the law, and he was a great danger to the public, therefore he thought the time had come for the Council to withdraw the qualifying adjectives and

Hosted by Google

adverbs in their regulations. This of course must be done carefully, and therefore he proposed that the Executive Committee should be instructed to take up the matter.

Dr. CAMERON, in seconding the motion, said there exists, at all events in England, a very large class of persons who were not merely unqualified assistants, but who never intended to be anything else. It was a separate profession outside their own profession, and after a certain time, on the strength of being members of this separate profession, they married and reared families and had no intention of leaving it, and when it was suggested that steps should be taken in any way to interfere with their work this Council was told that it would be cruel and inhuman to these men and their wives and families to interrupt in any way their success in this particular profession. Although the Council did not explicitly approve of the employment of these persons, they approved in this sense, that they took no steps to interfere with them until some qualified practitioner was brought before the Council and the complaint laid against him, that he had substituted the work of one of these men entirely for his own. If the charge failed to be substantiated, the Council simply dismissed the case without any expression of opinion in regard to the wrongful attitude which the practitioner had assumed in employing such a person at all. He thought the time had come when the Council might give some such expression of opinion as that a man in whose case six, or eight, or ten, or any other number of years had elapsed since he was registered as a medical student should not be allowed to be employed as an unqualified assistant. That, at all events, was a point which the committee might very well consider.

Mr. BRYANT said he desired to support the motion, and as a member of the Executive Committee to express his pleasure that they had anticipated this request. Not long ago the Executive Committee appointed a sub-committee to draw up a memorandum upon the growth of opinion in the Council in regard to the employment of unqualified assistants and covering unqualified assistants. The drawing up of the report fortunately fell into his hands, and here was the report. He would not trouble the Council with it now, but they came to certain conclusions, and if this report had been laid before the Council it would have been his duty to propose certain resolutions bearing on the subject. The first resolution would have suggested that a definite time should be fixed—say, 1900—when unqualified assistants now practising medicine, surgery, and midwifery would be treated as offenders against the Medical Acts and regarded as guilty of infamous conduct in a professional respect. He would also have proposed that notice of the Council's regulations and intentions should be put into very clear language so that they could not possibly be misunderstood and sent to every member practising in the United Kingdom. Therefore, he hoped this reference would be made to the Executive Committee, and that with the aid of their lawyers the matter would be thrashed out.

The motion was then agreed to.

Covering in the Profession: the Excuse of Ignorance.

The next item on the programme of business was the following motion, to be proposed by Dr. RENTOUL and seconded by Dr. LEECH, viz.:—

"That in order to lessen the number of offences under the Penal Sections of the Medical and Dental Acts the General Council supply to the examining bodies under these two Acts copies of their rules relating to covering and other offences against these Acts, with a request that these examining bodies supply a copy of such rules to each person upon his first obtaining his qualification.

"That each Branch Registrar, upon registering a qualification, supply a copy of such rules to the person when first registered.

"That each Branch Registrar shall supply to each person on first registering a qualification a copy of the Medical Register and of the Standing Orders of the General Council of the date upon which the person is first registered."

Sir WILLIAM TURNER suggested to Dr. Rentoul that in view of the decision just arrived at instructing the Executive Committee to frame a revised code of rules it would be better to postpone this motion.

Mr. BRYANT joined in this suggestion.

Dr. LEECH, as the intending seconder of the motion, made an appeal to Dr. Rentoul to postpone the matter.

Dr. RENTOUL asked whether the Council would agree to this motion being sent as an instruction to the Executive Committee.

Sir WILLIAM TURNER said he could not agree to it as an instruction, although he was quite willing that it should be considered by the Executive Committee. The proposition that this Council should circulate amongst all the members of the profession its Standing Orders which were intended for its own internal administration was one that the Council should under no consideration accept.

Mr. BROWN said he would second Dr. Rentoul's motion, and proceeded to address the Council.

Dr. BATTY TUKE interrupted him saying that his remarks were not relevant to the subject, and moved the previous question.

Mr. BRUDENELL CARTER seconded the previous question.

On a vote being taken the previous question was carried by 16 votes to 4. Eight members did not vote and two were absent.

The Council accordingly proceeded to the next business.

Medical Aid Associations.

It was agreed that the communications in regard to medical aid associations received by the Executive Committee on May 24th should be referred to the Medical Aid Association Committee.

Dr. GLOVER proposed that the committee should consist of Mr. Teale, Dr. Leech, Dr. Bruce, Mr. Bryant, Dr. Rentoul, and Dr. Glover.

Dr. RENTOUL asked if the committee was paid. If it was not he could not act on it.

Mr. TEALE said that the committee was authorised to spend a sum not exceeding, unless with the consent of the Council, £100. The committee, after appointment in 1892, had several meetings, and those who came from a distance got their travelling expenses.

Dr. RENTOUL: But is that fund exhausted?

Dr. MACALISTER: Yes.

Dr. LEECH said he should like to have his name withdrawn from nomination. He thought the committee had come to a wrong decision on this subject, and he should not like to serve further on it.

Mr. BRYANT thought that as the committee would be different from the former committee Dr. Leech should not assume that the conclusion of the committee it was proposed to appoint would be the same. He himself trusted it would not be the same. It would be a pity if they could not retain the services of a man who had gone over the whole of the ground.

Dr. GLOVER proposed Dr. Church in place of Dr. Leech.

Mr. TEALE seconded the nomination of the committee with this alteration.

Dr. RENTOUL moved as an amendment:—

"(1) That the General Medical Council is of opinion that friendly and similar societies have been established chiefly for the purpose of providing sick pay, funeral expenses, widows and orphans annuities, and other grants to their members; (2) that the General Medical Council considers that it would be much to the advantage of the public health if all such societies either (*a*) altogether ceased to employ medical practitioners to act as medical officers to such societies, or (*b*) that the plan be adopted of each society allowing each member to call in any practitioner whom the member prefers to be treated by, the society agreeing to pay the fees of such practitioner; and (3) that the General Medical Council therefore considers that medical practitioners should refuse to act as medical officers to friendly and medical aid associations."

In support of this proposal Dr. Rentoul said that this question of medical aid associations could scarcely be dealt with properly by this General Medical Council. He failed to see how they could attack the high as well as the low. For instance, Guy's Hospital was advertising that any person could obtain medical treatment and medicine for 3*d*. a week. It was customary to sneer at 6*d*. a visit, but a man had much more dignity in accepting 6*d*. a visit than 3*d*. a week. Guy's Hospital had appointed four men at 100 guineas a year to take charge of this department of theirs. If these men were to be brought before the Council for unprofessional conduct it would be less time wasted than for the Council to handle the subject of medical aid associations.

Mr. THOMSON seconded the amendment.

Mr. BRYANT said Guy's was his own hospital, and he must repudiate in the strongest words he could use the accusations which had just been made against it. Dr. Rentoul was entirely in the wrong, and if he would take five minutes' trouble to look into the matter he would see that, and he would probably come back next session and apologise for bringing forward such a gross accusation.

Dr. RENTOUL: Will you bring forward any documents in disproof?

Mr. BRYANT: It is for you to bring forward documents.

The PRESIDENT said that Mr. Farrar, their solicitor, gave

Hosted by Google

the opinion that the amendment was altogether outside the statute within which the Council acted, and therefore he had to rule it out of order. It was not in such a way the Council could express an opinion. The subject had been committed to a committee and they might bring up what report they liked.

Mr. BROWN moved, as an amendment, that the subject be dealt with, not by the committee nominated, but by the English Branch Council, who seemed to have little or no work to do.

Dr. RENTOUL seconded this amendment.

On a show of hands being taken, only two members voted for the amendment, which accordingly was rejected. Before the motion was further proceeded with,

Mr. BRYANT said that as Dr. Rentoul had formed an opinion on the subject he was hardly fitted to be a member of the committee.

Mr. TEALE thought it would be an advantage if Dr. Rentoul were on the committee. He had seen one side of the subject, and there was a great deal more in it than appeared on the surface.

Dr. RENTOUL asked if his expenses would be a first claim on any money the Council sanctioned the expenditure of by this committee.

Dr. HERON WATSON remarked that he sat on a committee in the first year of his membership of the Council, and none of the members got either their travelling or hotel expenses. They were all quite willing to do the work *ex gratia*, and he was willing enough to continue to do so. The claim for payment showed a totally new spirit entering the Council.

Dr. RENTOUL said he was a general practitioner, and had no wish to come to this Council, but his fellow practitioners had elected him. He had to pay his assistant while he was in London at great expense, and he should like to get some *quid pro quo* while he was on Council business.

Sir DYCE DUCKWORTH pointed out that in former days they would have heard nothing of this, and he regretted that such a mercenary spirit should come in. He totally disapproved of it.

The motion proposed by Dr. Glover was then agreed to.

Payment of Penal Committee.

Dr. RENTOUL moved:—

"That the same payments be made to members attending a meeting of the Penal Cases Committee as are now made to members attending a meeting of the General Council."

He said it was felt among members of the profession that the Council had not given that due attention to the penal sections of the Act that they ought to give, and the fact that they had this session re-constituted the Penal Committee was an indication that the Council were not pleased with the condition of affairs which had hitherto prevailed. He thought if the committee were paid it would have work better done. Although the expenditure of the Council amounted to between £7000 and £8000 annually only some £800 was spent on the penal cases.

Mr. BROWN, in seconding the motion, thought the country members might get payment at the rate of 5 guineas a day, but the payment to the town members might be restricted to 2 guineas a day.

Dr. MACALISTER altogether objected to this motion. They did not yet know what the Penal Committee was going to do, and only when they had had some experience of the new procedure would they enter upon the question of remuneration, if it ever was to be raised at all.

Mr. BRUDENELL CARTER said the proposition was altogether unnecessary. If general practitioners found it inconvenient to attend they had better retire.

Dr. RENTOUL: With pleasure.

Mr. BRUDENELL CARTER continued to say that Dr. Rentoul had told them earlier in the day that all unpaid work was bad work. He had not thought of hearing Dr. Rentoul say that, for he thought Dr. Rentoul had done more unpaid work than any other member of this Council, and it was testimony to the excellency of the work that his professional brethren had sent him to the Council. If he was not able to come to the committee he could stay away, and the other members would, he dared to say, be able to discharge the business.

As only two members voted in support of it the motion was rejected.

The Case of Edmund Evance Hooper.

The Council *in camerâ* resumed the adjourned consideration of the case of Edmund Evance Hooper. On strangers being re-admitted to the chamber,

Sir WILLIAM TURNER, who occupied the chair, said the Council had now deliberated on Mr. Hooper's case. They had taken into consideration the promise given by Mr. Hooper that he would cease to employ an unqualified assistant, and the decision they had come to was this—that the further consideration of the case should be adjourned until next session. Mr. Hooper would be called to appear before the Council during that session, and would have to produce evidence that he had not in the interval been covering an unqualified assistant.

Mr. HOOPER: I am quite satisfied. Thank you for your courtesy.

Fines under Medical Acts.

With Sir RICHARD QUAIN again in the chair,

Dr. GLOVER moved that a committee consisting of the President, Sir Dyce Duckworth, Mr. Bryant, Mr. Carter, and Dr. Glover be appointed to prepare a memorial to the Home Secretary, and a copy of the same as a petition to the House of Commons, in respect of fines accruing under the Medical Act or Acts within the Metropolitan area.

Dr. MACALISTER seconded, and the motion was agreed to.

A draft of the proposed memorial, read by Dr. Glover, showed that fines accruing in the district in question are diverted from the General Medical Council to whom they were assigned by the Medical Act of 1858. Such as arise in the Metropolitan police courts are received and detained by the Receiver of Police. This has had the effect of stopping prosecutions within the Metropolitan area. On several previous occasions the Council have made representations to the Government on this unfortunate state of the law. The Home Secretary on July 17th, 1891, admitted the facts and held out some hope of eventually effecting an alteration such as the Council desire, but nothing has since been done. As prosecutions are never begun by the police themselves and as the desired alteration will involve no cost to the Treasury, the Council are more hopeful now of obtaining redress.

Dr. GLOVER proceeded to say that he saw a number of members of Parliament a week or two ago on this subject, among them being Dr. Farquharson, Sir Walter Foster, Sir William Priestley, and Mr. Jesse Collings (the Under Secretary for the Home Department), the last named of whom was in charge of the Metropolitan Police Courts Bill. All of them were most willing to promote what the Council desired. He had also seen Mr. Bucknill, who said he would be happy to do anything he could to further the Council's views, and he took in hand a resolution on the subject drawn up by Mr. Farrar. There was therefore some reason to believe that they would get what they wanted with this qualification—that Mr. Collings had said the present Police Courts Bill was for a very limited purpose, beyond which it might not be possible to go; but if they did not succeed in connexion with the present Bill there would be another opportunity when the Bill on the question of the revision of the police of London was brought into Parliament.

It was agreed that the committee should prepare the memorial in accordance with the terms of the draft now submitted to the Council, and that the President should sign it on behalf of the Council and have both memorial and petition forwarded to the proper quarters.

Duration of Speeches.

Mr. BRUDENELL CARTER moved that it be referred to the Executive Committee to consider and report whether it would be desirable to pass a standing order to the effect that no member of the Council, other than the president or the chairman of a committee introducing a report, should speak to any motion for more than ten minutes without the permission of the Council being asked from the Chair and granted by resolution moved, seconded, and carried without debate.

Dr. LEECH seconded the proposal.

Mr. BROWN thought the Council were entitled to hear some good reason why a proposal of this sort was introduced at this particular juncture, seeing that the Council had gone on for thirty or forty years without such a standing order.

Dr. GLOVER hoped that Mr. Carter would not press the motion, as not only was it at the present moment somewhat invidious, but it took away certain of the privileges members of the Council had always enjoyed.

Dr. RENTOUL supported the views of Mr. Brown and Dr. Glover. He said that if any members of this Council wished to obstruct they could do it, because they could talk and take divisions on every motion that was broug t up in Council, and he would promise to talk upon and · allenge

Hosted by Google

a division on every motion that came before the Council if such a standing order came into operation. He said that now as a protest against the proposal being proceeded with.

On a show of hands 14 voted for the motion and 10 against. On the names being taken on Dr. Rentoul's demand, the vote was 17 for to 10 against.

Assistant Apothecaries.

Dr. RENTOUL moved:—

"That the Registrar be now instructed to obtain a return showing:—1. The number of persons who have applied during each of the last twenty years to be examined for the diploma of Assistant Licentiate of the Apothecaries' Society, London, and of the Apothecaries' Hall, Dublin, under the Apothecaries Act, Eng., 1815, SS. 17 and 18, and under the Apothecaries' Act, Ireland, 1791, SS. 18 and 19. 2. The number of persons who have been refused such diploma after examination 3. The sum paid for such examination and diploma. 4. The privileges conferred by such diploma upon the holder of such. 5. Period of study and curriculum required from candidates for such diploma. 6. The form of diploma granted to such persons."

In supporting this proposal Dr. Rentoul said that the holders of these diplomas were practitioners, though he did not think the Council knew of them, and he doubted if they knew that the London Apothecaries' Society under the Act named could constitute other fifty-two bodies throughout England and Wales to grant licences to these assistant apothecaries. He had repeatedly made inquiries at the society on the subject, but he had failed to get information in answer to his letters. A fee of £1 6*s*., he understood, was paid in Dublin for the diploma of assistant licentiate, and that was one reason why he asked for the several particulars included in his motion.

Mr. THOMSON, in seconding the proposal, said that until his attention was drawn to the matter he was quite unaware that such a body as assistant apothecaries existed. It appeared that such a body did exist, and that certificates were granted to them and were used in England as representing gentlemen qualified to practise. They could not register, but the certificates were used to enable them to practise. All that the motion asked for was information.

Sir WILLIAM TURNER pointed out that the Medical Act said nothing about assistant licentiates either of London or Dublin. The Council had therefore only to do with the certificates of licentiates. They knew nothing about assistant licentiates.

Dr. MACALISTER: Either these assistants are legal or not.

Dr. RENTOUL: The Acts have never been amended.

Dr. MACALISTER: They are outside the Medical Council's functions, and nothing would be gained by inquiry into what is legal and outside our functions.

Mr. BRUDENELL CARTER said that Dr. Rentoul's own difficulties in getting answers to his letters suggested that "ask for" should be put in the place of the word "obtain" in the proposal. He, however, was under the impression that so far as the London Society was concerned the whole thing was obsolete. There used to be these assistants, but his impression was that nothing of the kind had been done for many years, since the passing of the Act which constituted the Pharmaceutical Society. If it was the wish of the General Medical Council he would undertake to ascertain all the facts and inform the Council of them.

Mr. TICHBORNE hardly understood what Dr. Rentoul meant by assistant licentiates and the Dublin Apothecaries' Hall had none of them and did not know the term. Any assistants to whom the Hall gave certificates were not allowed to act except under the immediate supervision of their masters. He was sure the Dublin Hall would be delighted to give every information they possibly could.

Mr. BROWN mentioned that when he himself went up to the London Apothecaries' Society for examination a number of young men went up at the same time for the assistant apothecary examination. The thing, therefore, was not what was to be described as obsolete.

Mr. BRYANT suggested that as the representatives of the societies had promised information the motion should be withdrawn.

A vote was taken and the motion was rejected.

Registering a Foreigner.

The Council received the following report from the English Branch Council:—

"That the English Branch Council recommends the General Council to register the name of Dr. Bruno Beheim-Schwarzbach, Lic. Fac. Phys. Surg. Glasg. 1880."

On the motion of Dr. MACALISTER, seconded by Mr. BRYANT, the report was adopted.

Midwives Registration Bill.

On the motion of Sir WILLIAM TURNER the following report was received and entered on the minutes:—

"The Business Committee recommend that the committee to be appointed for the consideration of the Midwives Registration Bill, referred to the Council by the Privy Council, consist of the following members: Dr. Thorne Thorne (chairman), Mr. Carter, Mr. Brown, Dr. Rentoul, Dr. Glover, Dr. Cameron, and Dr. Atthill."

Dr. RENTOUL asked if this committee was to be paid.

Sir WILLIAM TURNER replied that on the last occasion when a similar committee was appointed the members met only during the sitting of the Council, and consequently there was no occasion for any special payment.

Dr. RENTOUL: If I cannot have a guarantee that it will meet only during the meeting of the Council I shall ask you to withdraw my name.

Sir WILLIAM TURNER: The committee is not to report till the November session, and the committee can meet at the same time as the Council.

Dr. RENTOUL: If the committee meet during the meeting of the Council I shall be glad to go on the committee, otherwise I shall not.

The report was adopted.

Sequel to a Penal Case.

The REGISTRAR (Mr. Allen) read the following notice, which was on the programme as to be moved by Dr. Rentoul and seconded by Mr. Thomson:—

"That the Registrar forthwith call the attention of the Apothecaries' Society, London, to the case of E. E. Hooper and his 'Medical Assistant,' as heard before the Medical Council, and that the said Society be requested—if it think fit—to institute proceedings against the said unqualified person, under Section 20 of the Apothecaries Act, Eng., 1815 (55 Geo. III., cap. 194), who, it has been stated, is not an Assistant Licentiate of the said Society, E. E. Hooper being a Licentiate of the said Society. That a copy of the printed statements as presented to the Council be sent to the Apothecaries' Society."

Mr. FARRAR suggested that the object of the motion would be sufficiently carried out by calling the attention of the Apothecaries' Society to the case. It would hardly be becoming on the part of the Council to suggest to a constituent body what action they should take.

Dr. MACALISTER objected altogether to do anything at all at the present time, because Mr. Hooper's case was continued till November.

Dr. RENTOUL: It is known about the unqualified assistant.

Dr. MACALISTER: We have nothing to do with the unqualified assistant.

Dr. RENTOUL: Oh, yes.

Dr. MACALISTER: I propose that we defer action.

On a division the proposal of Dr. MacAlister was carried.

Petition of Mr. R. B. Anderson.

The next business on the programme was the petition of Richard Benjamin Anderson, of 30, Montague-place, Bloomsbury, and of the Island of Tobago, in the colony of Trinidad and Tobago. Mr. Anderson's case was before the Council in November last, but the basis of it may be summarised from the present petition. The petitioner, a Fellow and Member of the Royal College of Surgeons of England and a Licentiate of the London Society of Apothecaries, while practising in the colony retired from attendance on a patient after, it is said, due intimation that he was about to retire. An action was raised against him for this, and he was ordered to pay some £13 as damages and costs. An appeal by him was dismissed by the Colonial Court. He asked leave of the Court to appeal to the Privy Council, but they summoned him before them, and, besides imprisoning him for a week, ordered him to find bail to the extent of £1000 to make him pay the damages and costs in the original action against him. He came to this country and lost an action in the High Court against the colonial judge. The jury gave a verdict in his favour, but, on the ground that the defendant was a judge, judgment was entered for defendant. Since then he has been debarred action, but he wishes to appeal to the Privy Council and the House of Lords, and his petition, besides praying that he might be heard personally by the Council, asked "that either by a substantial contribution to the funds so being collected, your Council will assist in enabling, or by yourselves providing the necessary funds your Council will enable, your petitioner to bring his said appeals and carry them to a conclusion."

Dr. MACALISTER: The question is whether this petition should be entered on the minutes.

Dr. RENTOUL: You must enter it.

Hosted by Google

Mr. BRYANT moved that Mr. Anderson should be informed that his petition had been laid on the table.

Dr. RENTOUL: I move that the petition be entered in the minutes.

Mr. CARTER: That is an amendment.

Dr. RENTOUL: I have the right to move first. I have been asked by one of my constituents to present the petition. I have no right to refuse to do so. The Business Committee have considered it and allowed it to go on the programme, and have thus led the Council to believe that so far the petition is in order. I think it must go on the minutes.

Mr. CARTER understood that their solicitor had an opinion to give on this question.

Mr. FARRAR said he had consulted Mr. Muir Mackenzie earlier in the day on this subject, and their counsel was of opinion that any action on the part of the Council, either by way of interference or contribution from its funds, would be absolutely *ultra vires* and illegal. If the Council were to vote any part of its funds in aid of Mr. Anderson's appeal any registered practitioner might obtain an injunction from the High Court of Justice restraining such application of its funds, and any such application might be questioned in Parliament.

Mr. BROWN: I do not see how you can object to receive the petition. I second Dr. Rentoul's motion.

Dr. MACALISTER seconded Mr. Bryant's proposal, which was put into the following form:—

"That Mr. Anderson be informed that his petition has been laid before the Council, and that the Council is unable to take any action upon it."

On a show of hands being taken, only five members voted for Dr. Rentoul's proposal, most of the rest supporting Mr. Bryant's.

Dr. RENTOUL: I am very sorry to call for names.

The PRESIDENT: What is the possible good of it?

Dr. RENTOUL: I am claiming my right.

On the roll being called 5 voted for the proposal and 18 against.

The PRESIDENT thereupon put the question that Mr. Bryant's motion be adopted.

Mr. BROWN rose to a point of order. The motion, he said, stated that the petition had been laid before the Council. How had that been done?

The PRESIDENT: It has been on the programme.

Mr. BROWN wanted to know from the legal adviser if that was sufficient.

Mr. FARRAR: Certainly.

Dr. RENTOUL: I wish to speak on the motion.

Dr. MACALISTER: Dr. Rentoul has already spoken. He cannot speak again.

The motion was carried by 17 votes to 2.

The PRESIDENT: Will you have the names?

Dr. RENTOUL: I shall be very happy to have my name recorded.

Accumulation of Examinations.

Sir DYCE DUCKWORTH moved that the following report be received and entered on the minutes:—

"The Examination Committee, having reconsidered the motion of Mr. Teale of June 2nd, 1896, already reported upon on Nov. 30th, 1896, and remitted to the Committee for further consideration on Nov. 30th, 1896, have instructed the Chairman to communicate with the Chairman of the Education Committee with a view to a conference of the two committees on the questions raised in this motion."

Sir DYCE DUCKWORTH mentioned that he had conferred with Dr. Batty Tuke, and it was arranged to hold a conference, which would probably take place next session.

Dr. MACALISTER seconded, and the motion was agreed to.

Finance.

Mr. BRYANT, Chairman of Committee, in moving the adoption of the report by the Finance Committee on income and expenditure for the year 1896, stated that the interesting part of it was the following:—

"The average yearly income of the General and Branch Councils for the last seven years has exceeded the average yearly expenditure by £158 16*s.* 10*d.* But as this average yearly excess of income is considerably smaller than what has hitherto been usual, the following facts may be read with interest. The English Branch Council has during the last twenty years saved £14,141, its present assets representing £39,141. The Scottish Branch Council has saved during the same period £5088, with present assets £7088. The Irish Branch Council has been steadily losing ground, its assets having lessened from £2245, the amount at which they stood in 1877, to £801 18*s.* 5*d.*, the present value. To make the financial position of the Council quite clear it should be stated that in the four years, including 1889 to 1892, the excess of income over expenditure amounted to £5333 8*s.* 4*d.*, whilst in the four following years ending 1896 the expenditure was in excess of income to the sum of £2338 15*s.* 4*d.* The balance of the last eight years is thus still in favour of income by the amount of £2944 1*s.* 3*d.*

"To explain this marked increase of expenditure during the last four years it is only necessary to remind the Council that in 1892 the inspection of the examinations by a paid inspector was commenced, and that the expenses of this inspection during this period have amounted altogether to £3584 12*s.*—*viz.*, for the inspection itself, £1786 6*s.*, and for extra printing connected with it, £1798 6*s.*; the printing expenses of the Council for the four years ending 1892 having been £1938 12*s.*, whereas in the last four years they reached the total of £3736 18*s.* This sum did not include the expenses incurred for the new Pharmacopœia, which in all ways amounted during the last four years to the sum of £2608, whereas in the former four years it was only £1339, or about half.

"The conclusion is therefore evident that during the last four years extra expenses have been incurred, amounting altogether to £4863, or about £1200 a year; £3584 of this have been connected with the inspection of the examinations, which we may now consider closed for a time, and £1269 with the production of the Pharmacopœia, which will soon also not only come to an end, but become a source of profit rather than of expenditure."

Sir DYCE DUCKWORTH seconded the motion, which was agreed to.

Election of Committees.

The Executive Committee was re-elected. The Pharmacopœia Committee was re-appointed. For the Dental Education and Examination Committee Dr. Reid was put in the place of Dr. Fraser; and for the Dental Committee (a statutory committee appointed in terms of the Dentists Act) Mr. Carter was put in the place of Mr. Wheelhouse. The Finance Committee was constituted of Mr. Bryant, Sir Dyce Duckworth, Dr. Heron Watson, and Dr. Bennett. As the Penal Cases Committee under the new constitution Dr. Glover, Mr. Carter, and Mr. Bryant were appointed the members for England, Dr. Heron Watson the member for Scotland, and Mr. Thomson the member for Ireland. Dr. Bennett was put in the place of Dr. Wm. Moore as a member of the Students' Registration Committee.

The remaining committees were nominated as follows:—Examination Committee: Sir Dyce Duckworth, Mr. Bryant, and Mr. Teale for England; Sir William Turner, Dr. Heron Watson, and Dr. Pettigrew for Scotland; Sir Philip Smyly, Dr. Moore, and Mr. Thomson for Ireland. Education Committee: Dr. MacAlister, Dr. Glover, and Dr. Church for England; Dr. Batty Tuke, Dr. Gairdner, and Dr. Reid for Scotland; Sir John Banks, Dr. Bennett, and Mr. Thomson for Ireland. Public Health Committee: Dr. Thorne Thorne, Mr. Teale, and Dr. Church for England; Dr. Cameron, Dr. Bruce, and Dr. McVail for Scotland; Dr. Bennett, Sir P. Smyly, and Mr. Tichborne for Ireland.

Vote of Thanks to the President.

The PRESIDENT said the Council had now arrived at the end of their labours, and he congratulated them upon having got through much business.

Sir WILLIAM TURNER said: Before the Council rises its members would doubtless like to express their sense of the marvellous attention which the President has given to his duties, notwithstanding the serious illness through which he has recently passed. It is not customary for the Council to award a vote of thanks to its President at the conclusion of its meetings, but we cannot regard this as an ordinary occasion. There is a quality which we are apt to regard as especially characteristic of our race—a quality known by the short but expressive term "pluck." This quality has been displayed by the President on this occasion in no ordinary way. Throughout our meetings he has shown a virility and an energy most remarkable in one of his years, more especially considering all that he has recently gone through. I move that the best thanks of the Council be given to him for his services in the chair during the present session.

Dr. GLOVER seconded the proposal. The vote was not without precedent. But what was quite unprecedented in the Council, or anywhere else, was the exhibition of determination displayed by the President during the session. Such devotion to duty, such public spirit, such grip of the business of the Council, and, as Sir William Turner had said, such "pluck" in the peculiar circumstances of Sir Richard Quain's health, had never before, as far as he knew, been exhibited. The incident would long remain in the mind of the Council and of the profession.

Dr. PETTIGREW, in supporting the motion, said that he was fresh from reading a paper by the President to be read to the Royal Society dealing in a most interesting and original way with the question of the significance of the first sound of the heart.

The question on being put by Sir WILLIAM TURNER was carried by acclamation.

The PRESIDENT was much affected by the vote and returned his hearty thanks to the Council. He said what had moved him at all times in his work was a sense of duty.

Hosted by Google

His connexion with the General Medical Council had been always a matter of pride and pleasure to him, and his great desire had always been to maintain the honour and efficiency of the Council. When he had to lay down his office it would be with every wish for the welfare of the Council and of its members.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the College and are now entitled to register and to practise medicine, surgery, and midwifery, viz. :—

Ahlswede, Oscar Jacob Louis, L.R.C.P. Lond., Hamburg, Freiburg, and Berlin Universities, and St. Thomas's Hospital.
Amenabar, Julio Daniel, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Beadles, Hugh Stanley, L.R.C.P. Lond., St. Bartholomew's Hospital.
Bean, Louis Constantine, L.R.C.P. Lond., University College Hospital.
Betts, Edward Hetley, L.R.C.P. Lond., St. Bartholomew's Hospital.
Brebner, Arthur, L.R.C.P. Lond., University College Hospital.
Brodribb, Arthur Hubert, L.R.C.P. Lond., St. Mary's Hospital.
Brushfield, Archibald Nabauld, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester, and St. George's Hospital.
Burn, Alfred, L.R.C.P. Lond., St. Mary's Hospital.
Butler, Sydney George, L.R.C.P. Lond., London Hospital.
Callum, Harold Sidney Hill, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Campbell, Alfred, L.R.C.P. Lond., University of Sydney and Royal Infirmary, and Royal College of Surgeons, Edinburgh.
Carter, Arthur Burnell, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Case, Hugh Martin, L.R.C.P. Lond., Middlesex Hospital.
Chambers, John Miles, L.R.C.P. Lond., St. Thomas's Hospital.
Clowes, Ernest Francis, L.R.C.P. Lond., Guy's Hospital.
Cock, Herbert Edgcumbe, L.R.C.P. Lond., Guy's Hospital.
Coop, Edward John Ernest, L.R.C.P. Lond., Mason College, Birmingham, and Westminster and St. Bartholomew's Hospital.
Cooper, Harry Gordon, L.R.C.P. Lond., Cambridge University and Owens College and Royal Infirmary, Manchester.
Cowie, Robert Macnamara, L.R.C.P. Lond., King's College Hospital.
Crisp, George Bedford, L.R.C.P. Lond., St. Mary's Hospital.
Croker, Edward Ussher, L.R.C.P. Lond., St. Thomas's Hospital.
Dickson, Avery Winn, L.R.C.P. Lond., St. Bartholomew's Hospital.
Dodgson, George Stanley, Exams. for L.R.C.P. Lond., Cambridge University and Middlesex Hospital.
Dove, William Bathurst, L.R.C.P. Lond., Cambridge University and London Hospital.
Dykes, Percy Armstrong, L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and Guy's Hospital.
Dyson, Malcolm Goodworth, L.R.C.P. Lond., St. Bartholomew's Hospital.
Ellwood, Thomas Ashcroft, L.R.C.P. Lond., Charing-cross Hospital.
Evans, Charles Robert, L.R.C.P. Lond., Guy's Hospital.
Evans, John James, L.R.C.P. Lond., Edinburgh University.
Facey, Samuel Henry, L.R.C.P. Lond., St. Mary's Hospital.
Fegan, Richard Ardra, L.R.C.P. Lond., St. Bartholomew's Hospital.
Fenn, Joseph Hiorns, L.R.C.P. Lond., London Hospital.
Foote, Vivian Percival, L.R.C.P. Lond., Charing-cross and Westminster Hospitals.
French, Louis Alexander Wetherhead, L.R.C.P. Lond., University College Hospital.
Gairdner, John Francis Robert, L.R.C.P. Lond., University of Glasgow and London Hospital.
Gardner, Thomas Hudson, L.R.C.P. Lond., King's College Hospital.
Gilbertson, William, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
Goode, Henry Norman, L.R.C.P. Lond., St. Thomas's Hospital.
Granville, Alexander, L.R.C.P. Lond., St. Bartholomew's Hospital.
Gundlach, John, L.R.C.P. Lond., St. Bartholomew's Hospital.
Hall, John Spencer, L.R.C.P. Lond., St. Thomas's Hospital.
Hayward, William Curling, L.R.C.P. Lond., Charing-cross Hospital.
Hindley, Godfrey John Douglas, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.
Howard, Edwin, L.S.A. Lond., St. George's Hospital and Gloucester Infirmary.
Hunt, George Henry, L.R.C.P. Lond., Cambridge University and St. Mary's Hospital.
Hunt, Spencer, L.R.C.P. Lond., St. Bartholomew's Hospital.
Hyde, Reginald Henry, L.R.C.P. Lond., University College Hospital.
Ireland, Archibald Edward, L.R.C.P. Lond., St. Bartholomew's Hospital.
Jonas, Herbert Charlton, L.R.C.P. Lond., St. Thomas's Hospital.
Knowles, Arthur, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Knox, Robert George, L.R.C.P. Lond., King's College Hospital.
Lange, Massillon Henri Joseph, L.R.C.P. Lond., King's College Hospital.
Laurence, Bertram Eustace, L.R.C.P. Lond., St. Bartholomew's Hospital.
Lee, William Howe, L.R.C.P. Lond., Firth College, Sheffield, and London Hospital.
Le Geyt, Edward, L.R.C.P. Lond., London Hospital.
Littlehales, Arthur Gascoyne, L.R.C.P. Lond., Westminster Hospital.
Lovitt, Arnold Edward, L.R.C.P. Lond., London Hospital.
Low, William Stewart, L.R.C.P. Edin., University and Royal College of Surgeons, Edinburgh, and St. Thomas's Hospital.
Lower, Nynian Yeo, L.R.C.P. Lond., Guy's Hospital.
McClean, John Francis, L.R.C.P. Lond., St. Thomas's Hospital.
McKie, Gordon Mackenzie, L.R.C.P. Lond., King's College Hospital.
McSorley, Alexander Somerled, L.R.C.P. Lond., King's College Hospital.
Manasseh, Antonius Joseph, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Manning, Herbert Cambell, L.R.C.P. Lond., St. Bartholomew's Hospital.
Martin, James Sackville, L.R.C.P. Lond., Edinburgh University, St. Thomas's Hospital, and Firth College, Sheffield.
Mellish, John Stafford, L.R.C.P. Lond., St. George's Hospital.
Michael, Cyril Eden, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Mills-Roberts, Richard Arthur, L.R.C.P. Lond., Durham University and St. Thomas's Hospital.
Moore, Joseph, L.R.C.P. Lond., Royal Hospital, Belfast, London Hospital, and Oxford University.
Muir, Joseph Corbett, L.R.C.P. Lond., Cambridge University and Owens College and Royal Infirmary, Manchester.
Mundy, Herbert, L.R.C.P. Lond., St. Bartholomew's Hospital.
Myers, Walter, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
Nowell, Walter Salmon, L.R.C.P. Lond., Middlesex Hospital.
Parkinson, William, L.R.C.P. Lond., Firth College, Sheffield, and Yorkshire College and General Infirmary, Leeds.
Pearse, William Henry, L.R.C.P. Lond., Middlesex Hospital.
Pelle, William Hall, L.R.C.P. Lond., University College Hospital.
Phipps, John Hare, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Porter, Arthur Edward, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Prince, Peregrine Charles, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Ralstone, Robert Gow, L.R.C.P. Lond., Edinburgh University and St. Bartholomew's Hospital.
Read, Edward Henry, L.R.C.P. Lond., London Hospital.
Rouillard, Jean Antoine Abel, L.R.C.P. Lond., St. Thomas's Hospital.
Rowland, Sydney Domville, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Rygate, Arthur Montague, L.R.C.P. Lond., Durham University and Guy's Hospital.
Sandilands, John Edward, Exams. for L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Sanguenetti, Harold Herbert, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.
Seymour, Lionel William, L.R.C.P. Lond., St. George's Hospital.
Smith, Arthur Lionel Hall, L.R.C.P. Lond., University College Hospital.
Smith, Edwin Charles Temple, L.R.C.P. Lond., Mason College, Queen's, and General Hospitals, Birmingham.
Smith, Julius Hodgetts, L.R.C.P. Lond., St. Thomas's Hospital.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual general meeting and conference of this society was held on May 26th, at 20, Hanover-square, W. Dr. J. F. Payne, the president, gave his annual address, leading up to the subject which had been chosen for discussion—viz., "The Influence of Light and other Forms of Radiant Energy on the Skin and Tissues, i.e., the Effects of Roentgen Rays, Solar Light, and the Electric Light."—Dr. R. Bowles opened the discussion, and Dr. H. Radcliffe Crocker followed, touching more especially on x-ray dermatitis and the etiology of freckling.—The patients exhibited included two cases of Leprosy, shown by Dr. H. Radcliffe Crocker, and one of Seborrhœa of long standing, shown by Dr. Harrison, of Clifton.—The following officers were elected for the session 1897–98:—President: Dr. Joseph Frank Payne. Vice-Presidents: Dr. Robert L. Bowles, Dr. A. J. Harrison, Mr. Jonathan Hutchinson, Dr. Philip H. Pye-Smith, Mr. Buxton Shillitoe, and Dr. Walter G. Smith.

Hosted by Google

Treasurer: Dr. Jas. Herbert Stowers. Hon. Secretaries: Mr. George Pernet and Mr. William T. Freeman. The first annual dinner was held at Limmer's Hotel after the meeting, and was attended by upwards of fifty members and guests. The health of the guests was proposed by Mr. Jonathan Hutchinson, who referred in his speech to the great loss dermatology had sustained by the sad death of Dr. Feulard in the recent disaster at Paris.

DIPHTHERIA IN LONDON.—In the two weeks ended May 29th, the registered deaths from diphtheria in London have been 33 and 36 respectively. The former number in the week ended May 22nd was 3 below the corrected decennial average for the twentieth week of the period 1887-96. Camberwell was credited with 4 and Islington with 3 of the deaths, all the 33 being of young persons aged under twenty years; 7 were infants under one year of age, and 15 were under five years of age. On Saturday there were 785 patients suffering from the disease still in hospital, the admissions during the week having been 108, against 102, 107, and 94 in the three preceding weeks. In the outer ring there were 12 deaths registered from diphtheria, of which 3 were in Edmonton and 3 in West Ham registration districts, whilst 2 belonged to Willesden. Last week the 36 registered deaths from diphtheria in London were 2 in excess of the corrected decennial average for the corresponding week of the period 1887-96, only one being of a person aged over twenty years, and only one of an infant, though 24 were of children aged from one to five years. There were 3 deaths referred severally to Kensington, to Chelsea, and to Newington sanitary areas. On last Saturday there were 786 patients still in hospital, the admissions during the week having been 122. In the outer ring 7 deaths from diphtheria were registered in the week.

PRIZE DAY AT CHARING-CROSS HOSPITAL.—The scholarships, medals, prizes, and certificates awarded in the Charing-cross Hospital Medical School during the summer session, 1896, and the winter session, 1896-97 were presented to the successful competitors on June 2nd. Field-Marshal Sir John Lintorn Simmons, who was in the chair and made the presentations, delivered an address in the course of which he said: "It has given me great pleasure to have been able to distribute the prizes to those students who have won honourable distinction by their attention and industry during the present year. While congratulating them on their success I would remind them that the studies they have gone through are only a beginning of a lifelong labour in which they will have to exert their best energies in order to keep up with the progress of knowledge. As an old soldier now in the sixtieth year of service in Her Majesty's army, I with deep gratitude recall some of the benefits derived from the modern application of science in the treatment of diseases and wounds to which members of the military and naval professions are especially liable. For instance, during the Crimean War, anæsthetics were almost unknown and were never used until towards the end of the war, so that practically all operations were performed without them. Again, a very considerable number of officers and men died from gangrene and hospital fever, but now owing to the discovery of antiseptics these diseases have become almost unknown. To my mind one of the most remarkable features of our social condition in this country is the amount of gratuitous work done by members of your profession for the relief of suffering among the poorer classes, and we may be thankful that the sense of obligation felt by the public for the benefits derived from our great hospitals permits of their being maintained independently of all State assistance. Among the famous names associated with the school I would particularly mention those of Huxley the philosopher, Livingstone the traveller and missionary, and Llewellyn, who sacrificed himself to a sense of duty—men whose achievements may possibly be rivalled by some of those to whom I have the pleasure of presenting prizes in this the Diamond Jubilee year of our much-loved Queen." The Dean's report showed a very satisfactory state of affairs. In seven out of the eight groups of subjects at the examinations of the Conjoint Board the percentage of passes was above the average. Taking all subjects together the average percentage was 63, while the percentage of passes from Charing-cross was 73. At the first Fellowship examination of the Royal College of Surgeons 7 out of 10 candidates from Charing-cross passed, while the average percentage was only 37. The names of the prize-winners will be announced in a later issue.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The London Water Question.

THE second reading of the Bill of the Government to give further protection to water consumers in the metropolis will probably be taken on Monday, June 28th.

Dangerous Performances Bill.

The Bill to raise the limit of age within which dangerous performances are prohibited has received a second reading in the House of Commons.

Midwives Registration Bill.

The order for the second reading of this Bill was reached in the House of Commons on Wednesday, June 2nd, and was postponed until Wednesday, June 30th.

HOUSE OF COMMONS.

TUESDAY, MAY 25TH.

Enteric Fever among the Black Watch.

Colonel Wyndham Murray asked the Secretary of State for India whether an outbreak of enteric fever had occurred among the Black Watch Regiment at Subathu; whether the same regiment suffered severely from the same disease last summer in the same place; whether at that time the prevalence of the disease was accounted for by one of the reservoirs being infected with the particular bacillus which is associated with this disease, the water being found to be swarming with the characteristic microbes; what steps had been taken in the matter since last summer; and, if all precautions had been taken, what special advantages exist at this place that it should be maintained longer as a troop station.—Lord George Hamilton: A fresh outbreak of enteric fever has, I regret to say, occurred among the Black Watch which arrived at Subathu on March 24th last. A telegram from the Viceroy dated May 23rd states that eighteen cases have occurred, fourteen of which, however, are believed to have been contracted on the march up from the plains. Two cases have resulted fatally. Every possible sanitary precaution has been taken, and a thorough bacteriological examination into the cause of the disease is being made. A scheme for improving the permanent water-supply, involving the acquisition of land and springs, is being carried out, meanwhile the laying of a temporary pipe is nearly completed. Subathu, which is 4500 ft. above the sea, has a good climate and is not usually unhealthy.

THURSDAY, MAY 27TH.

Sale of Food and Drugs Bill

Mr. Balfour said, in answer to Mr. Dillon, that this Bill would be introduced, but he did not think there was much chance of its being passed into law during the present session. Of course, if it should unexpectedly turn out that there was a universal enthusiasm for the measure it might possibly be carried.

British Wines.

Mr. Lough asked the Chancellor of the Exchequer whether cider, perry, and British wines containing up to 15 per cent. of alcohol could be manufactured and sold without duty being paid on them; whether any statistics existed of the quantity of these beverages manufactured; and whether they were chiefly made in England; and, if so, whether any compensating immunity from duty could be granted to the native stimulants produced in Ireland and Scotland.—Sir Michael Hicks Beach replied that there was no duty on the manufacture of the liquors mentioned by the hon. Member, but a licence duty had to be paid on the sale of them by retail. There were no recent statistics as to the production of them, but it was found after an exhaustive inquiry which was made in 1887 that about one-sixth of the whole annual production of British wines came from Ireland, and it was estimated that about the same amount came from Scotland. These liquors contained very varying amounts of alcohol—some very little indeed.

FRIDAY, MAY 28TH.

Tuberculosis.

When the house was in Committee of Supply discussing the vote for the Board of Agriculture a debate took place on this subject. Mr. Channing asked the President of the Board whether the department had considered the advisability of extending the facilities for the voluntary use of the tests which were applied in Denmark and France in regard to tuberculosis. The results of the experiments on the Continent certainly tended to establish the accuracy of the test in the great majority of instances, and its general adoption would enable agriculturists to distinguish between healthy and unhealthy animals in their herds. Whatever might be the report of the Royal Commission there could be little doubt that the general adoption of the experiments, which had been carried out with some success by the hon. Member for Mid-Lothian (Sir Thomas Gibson-Carmichael) on his estate in Scotland, would result in enormous saving to farmers at comparatively little cost.—Mr. Lees Knowles took the view that nothing could be expected from the department until they had received the report of the Royal Commission.—Mr. Radcliffe Cooke suggested that the example of the United States and Canada should be followed and experimental farms established.—Mr. Walter Long, President of the Board of Agriculture, replying to these and other speakers, said that the report of the Royal Commission would be in their hands before long, and until then he was certainly not prepared to make any recommendations as to Government interference. He was not a believer in the system of experimental farms carried on by the Government, but he did believe in experimental farms attached to agricultural colleges and similar institutions, and he would gladly do what he could to assist educational centres, county councils, or great agricultural colleges to obtain land in order that practical instruction in agriculture might be given to students. He agreed that it was unfortunate to find how greatly orchards had been neglected in many

Hosted by Google

parts of the country, and he would consider the advisability of issuing a circular or leaflet on the subject.

MONDAY, MAY 31ST.

Charges against Scotch Medical Officers.

Mr. Weir asked the Lord Advocate, as representing the Secretary for Scotland, whether, as in the last report of the Local Government Board for Scotland allegations of a serious nature were stated to have been made against fifteen inspectors of poor, and that the Board was called upon to investigate eight charges against medical officers, he would state in what counties the inspectors of poor and medical officers were employed.—The Lord Advocate said that to supply the information requested would be an entire departure from ordinary practice, and would not, in the opinion of the Local Government Board, be to the interests of sound administration.

Nursing in Irish Workhouses.

Mr. Tulley asked the Chief Secretary to the Lord-Lieutenant of Ireland whether he could state the grounds on which the Local Government Board had annulled the appointment of Miss Walker as night nurse in Granard Union; and whether ladies with similar qualifications had been sanctioned in the neighbouring union of Longford, and also in unions in the north of Ireland.—Mr. Gerald Balfour said, in reply, that Miss Walker, aged twenty-two years, and without previous experience in nursing, was elected by the guardians at a salary of £10 a year. The Local Government Board had now informed the guardians that they could not sanction her appointment until they received a report from the workhouse medical officer stating that in his opinion she was qualified to discharge the duties of night nurse. The Board had added that if the guardians persisted in their refusal to secure the services of a trained nurse the medical officer might requisition such additional nursing assistance as he might require. The night nursing in Longford workhouse was in charge of the Sisters of Mercy, who were nurses in the workhouse, the duty being undertaken in rotation by these Sisters. The Board had repeatedly addressed boards of guardians relative to the necessity of appointing only trained and experienced persons to take charge of the workhouse infirmaries and fever hospitals, and wherever vacancies occurred the Board urged upon the guardians the desirability of offering such salaries as would induce qualified applicants to present themselves as candidates for the office of nurse.

TUESDAY, JUNE 1ST.

Irish Workhouse Infirmaries.

Mr. Carew asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in consequence of the defective condition of the nursing in Irish workhouse infirmaries and fever hospitals, he would consider the desirability of suggesting to the Local Government Board to appoint at least one or two lady inspectors, professionally qualified as doctors or nurses, to inspect the Poor-law fever hospitals and infirmaries, and who would also inspect the state of the women and children, the idiots, lunatics, and infirm.—Mr. Gerald Balfour replied that the major portion of the duties of an inspector of the Local Government Board could not be undertaken by a lady inspector. As to the expediency of appointing a lady inspector the question was not one on which he should be prepared to offer an opinion at present.

The Plague in Bombay.

Mr. Maclean asked the Secretary of State for India, whether the measures of segregation of the sick, and of the healthy from plague-infected houses, recently ordered by the Government of Bombay on the recommendation of medical men from Hong-Kong, were in substance urged upon that Government early in October, 1896, by the Surgeon-General with the Government of Bombay, and again in December by a committee of Bombay medical officers presided over by the late Surgeon-Major Manser. Whether the Surgeon-General in October advised medical examination of railway passengers at Kalyan and Virar, as being more effectual than inspection at terminal stations within Bombay limits, and whether the recommendation was disregarded by the Bombay Government for three and a half months, during which the plague was carried to numerous fresh centres of infection; whether, in the measures that had been adopted and the special appointments made to deal with the plague, the Bombay Government had acted in consultation with the Surgeon-General and the Sanitary Commissioner and on their recommendation; and whether he could lay upon the table copies of the report of the committee above referred to and of the recommendations of the Surgeon-General.—Lord George Hamilton said he was unable to answer the first two questions as to the origin and paternity of the measures taken to suppress plague in Bombay, but so far as he knew there had been no divergence of opinion as to the most effective measures of stamping out the pestilence, though there might have been differences of opinion as to the possibility of enforcing off-hand drastic measures. So far as he knew the Bombay Government had acted throughout in consultation with the Surgeon-General and the Sanitary Commissioner. As to the reports referred to he would inquire about them and consider whether they should be made public.
